Reboxetine

CLINICAL STUDY
013

December 15, 1995

Multicentre, Multinational Double-blind Study of the Activity and Tolerability of Reboxetine vs Placebo in the Continuation Therapy of Major Depressive Episodes (Phase III)

Final report of study
CTN013-FCE20124

Authors

Ban TA, Dubini A, Petroccione A, Castiglioni RA,

TABLE OF CONTENTS

STUDY CO-ORDINATION, MANAGEMENT AND REPORTING	2
CLINICAL INVESTIGATORS	3
TABLE OF CONTENTS	7
LIST OF ABBREVIATIONS AND TERMS	23
SYNOPSIS	24
1. INTRODUCTION	28
2. STUDY OBJECTIVES	29
3. INVESTIGATIONAL PLAN	29
3.1 Study Design and Plan - Description and Rationale	29
3.1.1 Overview and Justification	29
3.1.2 Protocol Amendments	30
3.2 Ethics	31
3.2.1 Ethics Committee	31
3.2.2 Declaration of Helsinki	31
3.2.3 Patient Information	31
3.3 Study Population	32
3.3.1 Inclusion Criteria	32
3.3.2 Exclusion Criteria	32
3.3.3 Withdrawal Criteria	33
3.3.4 Sample Size - Number of Patients Planned	33
3.4 Treatments	34
3.4.1 Treatments to be Compared	34
3.4.2 Identity of Test Treatments	34
3.4.3 Dose Selection and Timing	34
3.4.4 Method of Assigning Patients to Treatment Groups	34
3.4.5 Treatment Packaging and Blinding	35
3.4.6 Concomitant Therapy	35
3.4.7 Treatment Supply, Accountability and Compliance	36
3.5 Efficacy and Safety Variables	36
3.5.1 Efficacy	36
3.5.1.1 Hamilton Depression Rating Scale	36
3.5.1.2 Clinical Global Impression	38
3.5.1.3 Montgomery and Asberg Depression Rating Scale	39
3.5.1.4 Zung Self-Rating Depression Scale	39
3.5.2 Safety	40
3.5.2.1 Adverse Events	40

Pharmacia

Document 9550077

3.5.2.2 Clinical and Laboratory Tests	41
3.6 Study Procedures and Flow Chart	42
3.6.1 Schedule of Assessments	42
3.6.1.1 Schedule of Assessments - Open Treatment Phase	42
3.6.1.2 Schedule of Assessments - Double-blind Treatment Phase	43
3.7 GCP Compliance and Data Quality Assurance	43
3.8 Statistical Analysis	44
3.8.1 Power Considerations	44
3.8.2 Planned Analysis	44
3.8.3 Analysis Carried Out	45
3.8.3.1 Baseline Comparability of Treatment Groups	45
3.8.3.2 Efficacy Analyses	45
3.8.3.3 Safety Analyses	47
3.9 Data Management	49
4. STUDY PATIENTS	50
4.1 Disposition of Patients	50
4.2 Protocol Deviations	52
4.2.1 Compliance with Entry Criteria	52
4.2.2 Concomitant Medications	52
4.2.3 Response criterion (HAMD total score decreased by 50% or more) for admission to double-blind phase	52
4.2.4 Randomisation	52
4.2.5 Assessment Intervals	53
4.2.6 Withdrawals for Protocol Violation	53
4.3 Demographic Data	53
4.3.1 Severity of Depression	54
4.3.2 Previous History of Depression	56
4.3.3 Medical History	57
5. STUDY MEDICATION AND COMPLIANCE	58
6. CONCOMITANT MEDICATION	58
7. EFFICACY RESULTS	58
7.1 Open Phase of the Study	58
7.1.1 Hamilton Depression Rating Scale	58
7.1.2 Clinical Global Impression	59
7.1.2.1 Severity of Illness	59
7.1.2.2 Global Improvement	59
7.1.2.3 Efficacy Index	59
7.1.3 Montgomery-Asberg Depression Rating Scale	59
7.1.4 Zung Self-Rating Depression Scale	59
7.2 Double-blind Phase	60

7.2.1 Hamilton Depression Rating Scale	60
7.2.1.1 HAMD Total Score	60
7.2.1.2 HAMD Factors	61
7.2.2 Clinical Global Impression	62
7.2.2.1 Severity of Illness	62
7.2.2.2 Global Improvement	62
7.2.2.3 Efficacy Index	62
7.2.3 Montgomery-Asberg Depression Rating Scale	62
7.2.4 Zung Self-Rating Depression Scale	63
7.3 Efficacy Conclusions	63
8. SAFETY RESULTS	63
8.1 Safety Population and Extent of Exposure	63
8.1.1 Number of Patients in Safety Analysis	63
8.1.2 Total Drug Exposure	63
8.2 Adverse Events	64
8.2.1 Analysis of Adverse Events	64
8.2.1.1 Open Phase	64
8.2.1.2 Double-blind Phase	66
8.2.2 Adverse Event Summary	69
8.2.2.1 Severity of Adverse Events	69
8.2.2.2 Age- and Gender-Related Effects	69
8.2.2.3 Frequently Reported Adverse Events	70
8.2.3 Serious Adverse Events, Deaths and Adverse Events Leading to Withdrawal	72
8.2.3.1 Serious Adverse Events and Deaths	72
8.2.3.2 Adverse Events Leading to Withdrawal	72
8.3 Laboratory Tests	73
8.3.1 Open Phase of the Study	73
8.3.1.1 Summary Statistics of Laboratory Values	73
8.3.1.2 Urinalysis	73
8.3.1.3 Abnormal Laboratory Values	73
8.3.1.4 Abnormal Laboratory Values of Clinical Relevance	74
8.3.2 Double-blind Phase	74
8.3.2.1 Summary Statistics of Laboratory Values	74
8.3.2.2 Urinalysis	75
8.3.2.3 Abnormal Laboratory Values	75
8.3.2.4 Abnormal Laboratory Values of Clinical Relevance	75
8.4 Vital Signs	75
8.4.1 Blood Pressure and Heart Rate	75
8.4.1.1 Open Phase	75
8.4.1.2 Double-blind Phase	76
8.4.2 Body Weight	77
8.4.3 Body Temperature	77
8.5 Ophthalmological Examination	77
8.6 Electrocardiogram	78

LIST OF ABBREVIATIONS AND TERMS

AUC	Area under the plasma levels curve
b.i.d.	twice daily
BP	blood pressure
BUN	blood urea nitrogen
CGI	clinical global impression
CRF	case record form
CV	cardio-vascular system
DSM-III-R	diagnostic and statistical manual - 3rd edition - revised
ECG	electrocardiogram
ECT	Electroconvulsive therapy
GI	gastro-intestinal system
HAMD	Hamilton depression rating scale
HR	heart rate
MADRS	Montgomery-Asberg depression rating scale
NS	nervous system
R&D	research and development
REM	rapid eye movement
SD	standard deviation
SEM	standard error of the mean
Zung SDS	Zung self-rating depression scale

REBOXETINE - PROTOCOL 20124/013

SYNOPSIS

Name of Company: Pharmacia	Individual study table referring to part IV of the dossier Ref.: Vol.: Page:	(For national authority use only)
Name of finished product: Name of active ingredient(s): Reboxetine		
Title of study: Multicentre, multinational double-blind study of the activity and tolerability of reboxetine vs placebo in the continuation therapy of major depressive episodes		
Investigators: Prof M Versiani, Dr R Castiglioni, Prof K Ernst, Prof A Lipcey, Prof P Gaszner, Dr L Mehilanc, Dr Osztorharies, Prof A Szucs, Dr T Hortobagyi.		
Study centres: Federal University, Rio de Janeiro, Brazil; Hôpital Sainte Marguerite, Marseille, France; Neurologische Universitätsklinik, Rostok, Germany; Janos General Hospital, Budapest, Hungary; National Institute for Nervous and Mental Diseases, Budapest, Hungary; Tartu University, Estonia; Megyei Kórház Pszichiatriai, Győr, Hungary; Hollos Jozsef Megyei Kórház, Kecskemét, Hungary; Városi Kórház Pszichiatriai, Osztálya, Nagykanizsa, Hungary.		
Publication (reference): None		
Study period: May 90 - March 93	Clinical Phase: III	
Objectives: To assess the activity and tolerability of reboxetine in comparison with placebo in the maintenance therapy of Major Depressive Disorders.		
Methodology: In this prospective, double-blind, randomised, placebo-controlled, parallel group, multicentre and multinational trial, patients underwent an initial wash-out period of 1-2 weeks, after which they received reboxetine 4 mg b.i.d. for six weeks. Responders (50% decrease of the total Hamilton Depression Rating Scale (HAMD) score) were randomised to treatment with either reboxetine 4 mg b.i.d. or placebo for a maximum of one year or until relapse (total HAMD score increased by at least 50% and of at least 18). The response to treatment was assessed using the HAMD scale, Clinical Global Impression (CGI), the Montgomery and Asberg Depression Rating Scale (MADRS) and the Zung Self-Rating Depression Scale (Zung SDS). Safety and tolerability were assessed by the reporting of any adverse events and assessment of vital signs (supine and standing blood pressure and heart rate), laboratory tests, ECG and ophthalmological examination.		
Number of subjects (planned and analysed): 300 patients were to be recruited for the double-blind phase of the study. 358 patients from 9 centres entered the open phase and 286 patients from 8 centres were randomised to treatment with either reboxetine (145) or placebo (141). Three patients were randomised to treatment with either reboxetine (2) or placebo (1) but never received it. They were excluded from the analysis. Thus, 283 patients received randomised treatment.		
Diagnosis and main criteria for inclusion : Patients were diagnosed according to the DSM-III-R classification and were also assessed by the Composite Diagnostic Evaluation of Depressive Disorders (CODE-DD). The severity of depression was quantified using the HAMD scale. Criteria for inclusion were as follows: (1) Patients of either sex, of any race, aged 18 to 65 years, with a diagnosis of acute recurrence of Major Depressive Disorders, not accompanied by psychotic features (DSM-III-R) and not chronic in course, as shown by the CODE-DD variables: 'Acute onset' or 'Subacute onset' present and 'Prolonged duration' absent; (2) Initial (pre-treatment) total score for the 21-item HAMD and the Day 0 total score had to be ≥ 18 .

<p>Duration of treatment: Open phase: 6 weeks; double-blind phase : maximum period of one year or until relapse</p>		
<p>Reference therapy: Placebo (excipients alone) indistinguishable tablets unit dose: mode of administration: by oral route batch no.: SF1030, SF1111</p>		
<p>Criteria for evaluation:</p> <p>Efficacy</p> <p><i>Response:</i> HAM-D total score decreases equal to or greater than 50% compared to the baseline value (Visit 0). <i>Remission:</i> HAM-D total score lower than or equal to 10 (absolute value). <i>Relapse:</i> Increase in HAM-D total score equal to or greater than 50% compared with the value at randomisation (Visit 6) and HAM-D total score equal to or greater than 18 (absolute value). <i>Time to relapse:</i> Number of days elapsing between the randomisation date (Visit 6) and the date when the patient was first classified as "relapse". <i>Time to treatment failure:</i> Number of days elapsing between randomisation date (Visit 6) and date of relapse or of withdrawal from the study for any reason other than improvement. <i>Maintenance of the response:</i> Cumulative probability of the long lasting effect of the treatment based on the time to treatment failure</p> <p>Safety</p> <p>Reporting of adverse events, measurements of vital signs (supine and standing blood pressure and heart rate), laboratory tests, ECG, and ophthalmological examination.</p>		
<p>Statistical Method: The primary analysis of treatment effectiveness (main end-point) was based on the comparison of the proportion of patients experiencing at least one relapse in the long-term treatment period following randomisation, out of the total number of randomised patients, in each of the two treatment groups. A chi-square test was applied in order to test the null hypothesis.</p> <p>The time patterns of relapses in the two treatment groups, were described by the Kaplan-Meier method and compared by the log-rank test.</p> <p>The crude rate of patients who did not relapse at least once and who did not withdraw (unless because of improvement) during the first six and the following six months of the double-blind period, respectively, were compared between the two treatment groups by chi-square test, in order to test the maintenance of the response achieved in the open phase in the two periods separately. In addition, the relapse-free time pattern in the two groups was described according to the Kaplan-Meier method and between-treatment difference was tested by the log-rank test. The remission rate at the last assessment of the double-blind phase was calculated and the between-treatment difference tested (chi-square test).</p>		

Pharmacia

Document 9550077

<p>Name of Company: Pharmacia</p> <p>Name of finished product:</p> <p>Name of active ingredient(s): Reboxetine</p>	<p>Individual study table referring to part IV of the dossier</p> <p>Ref.:</p> <p>Vol.:</p> <p>Page:</p>	<p>(For national authority use only)</p>
<p>The cumulative risk of developing the first adverse event during the treatment period was estimated by the Kaplan-Meier method (open phase only). Furthermore, the weekly (run-in phase) or monthly (double-blind phase) frequency of patients presenting adverse events (either because of the onset of new events or because of the persistence of those previously developed) was assessed.</p>		
<p>Results</p> <p>358 patients entered the open phase of the study, 263 females and 95 males, with a mean age of 43.2 years. During the double-blind phase of the study, 143 patients received reboxetine and 140 received placebo. 79 reboxetine and 65 placebo recipients completed the study.</p>		
<p>Efficacy At the end of open reboxetine, 76% of patients were responders and 50% of patients were in remission (HAMDD total score 10 or less). At the last assessment of the open reboxetine treatment, the HAMDD total score was reduced from 29.6 at baseline to 12.9, the MADRS total score from 18.4 to 7.8, while the percentage of patients whose condition was "very much improved" and "much improved" according to CGI scores was 45.8 and 31.3, respectively.</p> <p>Among the 133 responder patients randomised to reboxetine, 21.8% relapsed during the long-term treatment, while 56.1% of the 132 responder patients randomised to placebo relapsed, the between-treatment difference being highly significant ($p < 0.01$). The time pattern of the relapse rate analysed according to the Kaplan-Meier method indicates a significantly increased risk of relapse on placebo compared with reboxetine ($p = 0.0001$). The proportion of patients in remission at the last assessment of the double-blind treatment phase was significantly higher on reboxetine (78.2%) than on placebo (44.7%) ($p < 0.001$).</p> <p>These results are confirmed by the analysis of the secondary efficacy variables. In the 133 responder patients randomised to reboxetine, the mean HAMDD score was reduced from 29.2 at baseline to 8.8 at week 6 and to 5.9 at Week 52 in the 76 assessed patients still on maintenance reboxetine. In the 132 responder patients randomised to placebo, HAMDD scores fell from 30.1 to 9.1 at Week 6 but increased to 11.1 at Week 52 in the 62 assessed patients still on treatment. Similarly, the mean total MADRS scores fell from 5.3 at Week 6 to 3.1 at Week 52 in the 76 assessed patients still on maintenance reboxetine, compared with a rise from 5.3 to 7.0 in the 62 patients on placebo. The percentage of patients whose CGI score was "very much improved" increased from 62.4% at Week 6 to 94.7% at Week 52 on reboxetine in contrast to a marginal increase from 57.6% to 64.5% at Week 52 on placebo.</p> <p>The additional analysis of the frequency of absence of relapse during the initial six months and subsequent six months of treatment indicates that the advantage over placebo in the maintenance of the response is present also in the second half of the one year treatment period (88.0 vs 59.2% of the reboxetine- and placebo-treated patients, respectively).</p> <p>Safety: All the patients who received study treatment were included in the safety analysis, i.e. 358 patients in the open phase and 283 patients (143 reboxetine, 140 placebo) in the double-blind phase of the study.</p> <p>During the open phase of the study, 52% of the patients reported adverse events and 3.6% discontinued reboxetine medication due to adverse events. Most frequently reported were dry mouth (19% of the patients), constipation (17%), urinary hesitancy/retention and increased sweating (8%), tachycardia and insomnia (6% each), and decreased libido (5%). The occurrence of newly reported adverse events was similar on reboxetine and placebo during the double-blind phase of the study; 40/143 reboxetine recipients reported 56 adverse events compared with 32/140 placebo recipients who reported 48 adverse events; however, the prevalence of adverse events was higher in the reboxetine than in the placebo group and discontinuation due to adverse event was more frequent on reboxetine (4.2%) than on placebo (1.4%). Most frequently reported was constipation (8% on reboxetine, 4% on placebo). The majority of adverse events were mild. Adverse events were reported more frequently by men than women, particularly on reboxetine. This was particularly the case for urinary hesitancy, urinary retention and decreased libido. There were three serious adverse events during the study (suicide and generalised convulsive episode on open reboxetine, hallucinations on placebo). The one death was the result of suicide.</p>		

Pharmacia

Document 9550077

Name of Company: Pharmacia Name of finished product: Name of active ingredient(s): Reboxetine	Individual study table referring to part IV of the dossier Ref.: Vol.: Page:	(For national authority use only)
<p>There was no indication of modifications in laboratory tests that were of clinical significance.</p> <p>Vital signs were not modified to any significant extent, with the exception of heart rate, which was significantly increased (20% or more) under reboxetine to values of 100 beats/min or higher in approximately 10 to 15% of the patients, also on long-term treatment and particularly on standing.</p> <p>No indication of effect on cardiac function emerged from ECG recordings. The ophthalmological examination did not provide indications of treatment related changes.</p>		
<p>Conclusions: The efficacy of reboxetine maintenance therapy in responders, as measured by HAM-D, MADRS and CGI scales, was markedly superior to that of placebo in patients with major depression, when administered for up to one year. The tolerability of reboxetine administered on a long-term basis was highly acceptable, as shown by the safety profile which was marginally superior to placebo for the incidence of adverse events and clinically significant tachycardia and similar to placebo for modifications of other vital signs, haematology and blood chemistry tests, ophthalmological and ECG examinations.</p>		

1. INTRODUCTION

Reboxetine (FCE 20124 or (2RS, α RS)- 2-[α -(2-ethoxy-phenoxy) benzyl] morpholine) is a new chemical compound which is highly potent in the pharmacological and biochemical tests predictive of antidepressant efficacy such as reserpine antagonism, norepinephrine reuptake inhibition and REM sleep latency increase [1]. Reboxetine also demonstrates the ability to prevent the effects of clonidine, an α_2 noradrenergic receptors agonist, after a single oral dose, in an animal model where tricyclic antidepressants were active only upon repeated administration [1]. Therefore, reboxetine was hypothesised to exert antidepressant efficacy of faster onset than the antidepressants currently available in depressed patients. In addition, comparison with imipramine 75 mg in a Q-EEG study in healthy volunteers revealed that reboxetine does not possess the marked sedative activity of imipramine, but rather psychostimulating properties [2, 3].

The pharmacokinetic properties of reboxetine have been evaluated following administration of single oral doses to healthy volunteers [4]. Average peak levels were observed 2 hours after administration, with remarkably stable levels 1-6 hours after administration; reboxetine plasma half-life was estimated as 13.2 hours and circulating radioactivity was accounted for principally (73% of AUC) by unchanged reboxetine.

An early phase II, 4-week, multicentre study in 98 patients in which reboxetine was administered at fixed-dosing doses, with maximum doses between 4 and 12 mg, showed that the compound was well tolerated at doses of up to 10 mg/day [5].

A double-blind parallel group multicentre study in 258 patients hospitalised due to a major depressive episode compared maximum doses of 8 mg of reboxetine with 200 mg of desipramine and placebo administered over a period of 4 weeks [6]. Reboxetine was found to be more effective than placebo with decreases $\geq 50\%$ in Hamilton Depression Rating Scale (HAM-D) at the end of treatment in 63% of patients (36% under placebo and 46% under desipramine). These decreases were present after 14 days of treatment in 31% of reboxetine patients and 22% of desipramine patients. More reboxetine patients complained of headache and urinary retention, whereas more desipramine patients experienced dry mouth, sweating and blurred vision. Cardiovascular adverse events were relatively rare but appeared with slightly higher frequency in the desipramine group (hypotension and tachycardia).

Phase II results obtained in controlled conditions in short-term studies in patients suffering from Major Depressive Disorders indicate that reboxetine is an effective antidepressant agent with a favourable therapeutic index with respect to desipramine. It is, however, recognised that the treatment of the depressive episode up to apparent resolution of symptoms is insufficient and long-term treatment is recommended, particularly in the case of recurrent depression [7, 8]. The present study was designed to evaluate the efficacy of

reboxetine in the long-term, continuation therapy of major depressive episodes, and its tolerability during long-term administration.

2. STUDY OBJECTIVES

To assess the activity and tolerability of reboxetine in comparison with placebo in the maintenance therapy of Major Depressive Disorders.

3. INVESTIGATIONAL PLAN

3.1 Study Design and Plan - Description and Rationale

3.1.1 OVERVIEW AND JUSTIFICATION

This phase III study was designed as a prospective, double-blind, randomised, placebo-controlled, parallel group, multicentre and multinational trial of the long-term efficacy and tolerability of reboxetine administered orally for up to one year to adult patients with a major depressive episode who had previously responded to a 6-week course of reboxetine. The design of the study is shown overleaf.

A total of 300 patients with Major Depressive Disorders was to be recruited according to the inclusion and exclusion criteria, and an informed consent obtained from each patient before screening.

At screening, a full medical history and physical examination (including ophthalmological examination, chest X-ray and electrocardiogram (ECG)) were carried out together with measurement of vital signs and laboratory tests. Patients were classified according to the Diagnostic and Statistical Manual - 3rd edition - revised (DSM-III-R) classification and the severity of depression was quantified using the HAMD score. Patients were also assessed by the Composite Diagnostic Evaluation of Depressive Disorders (CODE-DD), a psychiatric composite diagnostic system, the results of which are reported separately in the Addendum 1 and 2 to the present report.

After an initial wash-out period of 1-2 weeks, patients received reboxetine 4 mg b.i.d. for 6 weeks. Responders ($\geq 50\%$ decrease of the total HAMD score) were randomised to treatment with either reboxetine 4 mg b.i.d. or placebo for a maximum of one year or until relapse (total HAMD score increased by at least 50% and of at least 18). Relapse rate and time was defined as the study end-point; the between-treatment difference in relapse rate and cumulative risk of relapse were statistically analysed by the chi-square test and the log-rank test, respectively.

Other variables used for measuring efficacy were the Clinical Global Impression (CGI), the Montgomery and Asberg Depression Rating Scale (MADRS) and the Zung Self-Rating Depression Scale (Zung SDS).

Pharmacia

Document 9550077

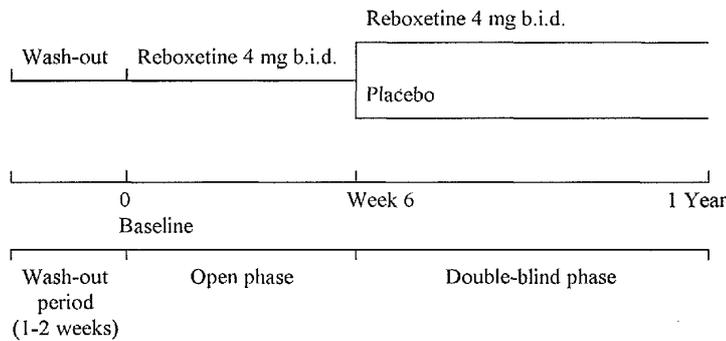

Safety and tolerability were assessed by the reporting of any adverse events and assessment of vital signs (supine and standing blood pressure and heart rate), laboratory tests, ECG and ophthalmological examination.

Patients willing to continue receiving the test treatment after completion of a one year treatment period could be maintained on the same medication under blind conditions until the completion of the last patient in the centre.

A follow-up visit was carried out in each patient one month after treatment discontinuation in order to monitor possible withdrawal reactions and collect information on any events since treatment discontinuation.

A copy of the final protocol can be found in Appendix 12.1.1.

Overall Design

3.1.2 PROTOCOL AMENDMENTS

A protocol amendment was introduced (January 24, 1991) to extend the wash-out period to 3-4 weeks in patients who had had previous treatment with fluoxetine.

Four centres initially expected to participate were not active in the study for organizational reasons which prevented the possibility of long-term patient follow-up (Laboratoire de Pharmacologie Clinique, Centre Hospitalier Ponchaillou, Rennes, France and Klinika Psychiatrikzna, Szczecin, Poland) or due to political emergencies (two centres at the National Psychiatric Hospital, Panama). To make up the deficiency in patient numbers, the study was extended to include centre numbers 11, 12 and 13 (See Appendix 12.1.4) in Hungary, while the population expected to be recruited was increased in centre numbers 1 and 10, in order to maintain the recruitment capacity needed for the proposed sample size.

Pharmacia

Document 9550077

3.2 Ethics

3.2.1 ETHICS COMMITTEE

Approval from the Ethics Committees or Institutional Review Boards (IRBs) of the participating centres, in accordance with the regulations and requirements of individual countries, had to be obtained before the study could be undertaken. It was the responsibility of each of the investigators to submit the study protocol with its attachments to the Ethics Committee or IRB. A central approval allowing the clinical evaluation of the product was required and obtained in Hungary and Estonia (for the specific protocol), while local approvals were required and obtained in Germany, Brazil and France. In the latter case, the approval was obtained on a draft version of the protocol, marginally different from the final one.

The investigators were responsible, in accordance with local requirements, for informing the Ethics Committee/IRB of any emergent problems, serious adverse reactions or protocol amendments.

The notifications of approval are kept in the Pharmacia's trial master file.

3.2.2 DECLARATION OF HELSINKI

The study was carried out according to the principles embodied in the Declaration of Helsinki, adopted by the 18th World Medical Assembly, Helsinki, June 1964, and amended by the 29th World Medical Assembly, Tokyo, October 1975, by the 35th World Medical Assembly, Venice, October 1983 and the 41st World Medical Assembly, Hong Kong, 1989. A copy of the Declaration of Helsinki can be found in Enclosure 10 of Appendix 12.1.1.

3.2.3 PATIENT INFORMATION

Before entering the study, an explanation of the nature, duration, purpose of the study and action of the compound had to be given to each patient in such a manner that he/she was made aware of the potential risks, inconveniences or adverse events that could occur, and could express his/her informed consent to participation. The proposed consent form is enclosed (Enclosure 1 of Appendix 12.1.1); local translations and/or the forms adopted in response to individual Ethical Committee suggestions can be found in the trial master file. The forms were signed by the patient or the investigator. In the latter case, the signature of a witness was required to testify that full information was given to the patient.

3.3 Study Population

Adult patients who were attending out-patient clinics or were newly admitted (within 2 weeks) to the Psychiatric departments of the participating centres were selected in accordance with the following inclusion and exclusion criteria.

3.3.1 INCLUSION CRITERIA

The criteria for participation in this study were as follows:

- Patients of either sex, of any race, aged 18 to 65 years
- A diagnosis of acute recurrence of Major Depressive Disorders, not accompanied by psychotic features (DSM-III-R) [9] and not chronic in course, as shown by the CODE - DD [10] variables: 'Acute onset' or 'Subacute onset' present and 'Prolonged duration' absent
- The initial (pre-treatment) total score for the 21-item HAMD [11] and the Day 0 total score had to be ≥ 18
- Informed consent was obtained from the patient and/or next of kin (see Section 3.2.3).

3.3.2 EXCLUSION CRITERIA

Exclusion criteria for patients recruited to this study were as follows:

- Patients with a first episode of Major Depressive Disorder
- History of Major Depressive Disorder associated with endocrine disorders: hypo- or hyperthyroidism (confirmed by rT_3 , followed by T_3 and T_4 in the case of negative findings on admission), adrenal insufficiency, etc
- Pregnancy (excluded by a pregnancy test at the end of the wash-out period)
- Refusal to use contraception during the study period
- Past history of drug hypersensitivity
- Participation in a clinical study with an investigational compound in the four weeks preceding the study
- Evidence of substance or drug abuse presently or within the past six months
- Chronic respiratory insufficiency

Pharmacia

Document 9550077

-
- History or presence of gastrointestinal, hepatic or renal disease, or other conditions known to interfere with the absorption, distribution, metabolism and excretion of drugs
 - History of seizures or serious brain injury; current evidence of clinically important haematopoietic or cardiovascular diseases; current evidence of urinary retention or glaucoma
 - Symptoms of any other important clinical illness in the four weeks preceding the study
 - Clinically relevant abnormal findings in the physical examination, laboratory tests and ECG at admission
 - Electroconvulsive therapy (ECT) in the previous six months.

3.3.3 WITHDRAWAL CRITERIA

Patients could be withdrawn from the study at any time for the following reasons:

- Voluntary withdrawal by the patient
- Unacceptable toxicity, defined as the occurrence of serious and unexpected adverse events or the persistence of non-tolerable signs or symptoms which were not alleviated by reducing the dose to the lower dosage level
- Lack of efficacy during the open initial treatment phase, which applied to patients who after completion of at least two weeks of treatment showed worsening of the global clinical picture (Clinical Global Improvement - CGI - see Section 3.5.1.2).

In the case of treatment discontinuation, the final complete battery of tests was carried out wherever possible.

3.3.4 SAMPLE SIZE - NUMBER OF PATIENTS PLANNED

Each of the 10 centres participating in the study were to recruit, within a period of one year, enough patients to collect a sample of 30 patients who fulfilled the criteria for entering the double-blind phase of the study, so that a total of 300 patients was to be recruited overall.

As already mentioned in Section 3.1.2., in 4 centres the study never started for logistical reasons, 3 new centers were included and recruitment was extended in centre numbers 1 and 10 to well above the foreseen patient sample. Recruitment was stopped after randomisation of 286 patients of the 358 recruited. The sample size was consistent with the one calculated for an "intent to treat" analysis.

3.4 Treatments

3.4.1 TREATMENTS TO BE COMPARED

After an initial wash-out period of 7 days (14 days in the case of monoamine oxidase inhibitors' administration, 3-4 weeks in case of fluoxetine following the protocol amendment), patients received reboxetine 4 mg b.i.d. for 6 weeks. Responders ($\geq 50\%$ decrease of the total HAMD score) were randomised to treatment with either reboxetine 4 mg b.i.d. or placebo (one tablet b.i.d.) for a maximum of one year or until relapse (total HAMD score increased by at least 50% and of at least 18).

3.4.2 IDENTITY OF TEST TREATMENTS

Indistinguishable scored tablets containing either reboxetine 4 mg plus excipients (Batch No: SF1032, SF1106) or excipients only (placebo, Batch No: SF1030, SF1111) were supplied by the Sponsor. Copies of certificates of analysis for the test treatments are presented in Appendix 12.1.5.

3.4.3 DOSE SELECTION AND TIMING

All patients recruited for the study received one tablet of reboxetine 4 mg b.i.d. from Day 1 to Day 42 (i.e., for 6 weeks). The daily dose of reboxetine was chosen on the basis of the results of the previously mentioned open dose finding study [5], in which daily doses of 8 to 10 mg were found to be associated with the best therapeutic index, and of the controlled phase II study vs desimipramine and placebo [6], where the 8 mg/day dose was proved to possess antidepressant efficacy. At the end of this open treatment phase, patients showing a response were randomised to treatment with either reboxetine 4 mg b.i.d. or placebo (one tablet b.i.d.) for a maximum period of one year or until relapse.

The treatment was administered in the morning (10 a.m.) and in the evening (6 p.m.). Treatment had to be taken at least 2 hours before or after meals.

The daily dose could be reduced to half a tablet (2 mg b.i.d. for reboxetine) in the case of emergence of non-tolerable signs or symptoms.

3.4.4 METHOD OF ASSIGNING PATIENTS TO TREATMENT GROUPS

A randomisation list balanced within each centre and every 4 assignments was originally generated for patient allocation either to reboxetine or placebo. In the list in order to make the patient unequivocally identifiable across centres by his assignment number, a progressive number from 1 to 390 was generated. The test treatments were labelled according to the randomisation sequence number. Each randomised patient was then identified by corresponding treatment number. In spite of the anticipated break down by centre of such a

sequential list, in order to minimize the waste of drug supply, the latter was shipped to the centres by complete blocks of four treatment each. This led to the utilization of study medication by centers other than those to which it was initially allocated.

At the end of the 6-week open treatment of the acute episode of major depression, patients eligible for the double-blind phase of the study were given by investigators an independent sequence number from the one assigned during the open phase, according to the time they complete it. Assignment of treatment was done in a double-blind fashion by matching this sequence number and the treatment box number.

3.4.5 TREATMENT PACKAGING AND BLINDING

For the initial open treatment of the acute episode, six amber glass bottles showing the patient number and the appropriate week of treatment (Week 1 to 6) were prepared for each patient. Each bottle contained the medication necessary for each of the first six weeks of treatment with reboxetine (i.e. 16 tablets, one 4 mg tablet b.i.d. and 2 additional tablets for possible losses).

For the double-blind continuation therapy in patients who responded, glass amber bottles showing the patient number and the treatment period Week 7-8, Week 9-10, Week 11-12, and so on up to Week 51-52 were prepared for all the patients. These bottles contained the medication necessary for the two-week treatment periods between visits up to a maximum of one year (i.e. 32 tablets of either reboxetine 4 mg or placebo, representing one tablet b.i.d. and 4 additional tablets for possible losses).

To ensure the double-blind nature of the study, indistinguishable test treatment in identical amber bottles was identified using double labels indicating the protocol number, patient number, treatment period, batch number and expiry date (Enclosure 2 of Appendix 12.1.1). The detachable half of the label was to be included in the appropriate place in the CRF when used.

The investigators were given individual sealed envelopes containing the information on patient's treatment, and these were to be opened only in case of emergency necessitating treatment identification. In the event of an emergency, the investigators were to notify the study monitor immediately (within 24 hours), and were to report a full description of the reasons for opening the code on the Adverse Event Form in the CRF. The sealed individual codes were to be returned to the Sponsor at the end of the study.

3.4.6 CONCOMITANT THERAPY

No concomitant medication was allowed during the study. In the case of events arising during the course of the study, non-psychotropic medications which were considered necessary for the patient's welfare could be administered and were not considered protocol

Pharmacia

Document 9550077

violations. The medication, dosage and frequency of administration were recorded on the CRF. Chloral hydrate was permitted at bed-time as a sleep inducer on an 'as required' basis.

3.4.7 TREATMENT SUPPLY, ACCOUNTABILITY AND COMPLIANCE

All drug supplies were handled under the direct responsibility of the investigators and held by the Hospital Pharmacy. The study monitors checked drug storage conditions during site visits.

The investigators were responsible for drug accountability and kept a record of the test compounds received from the Sponsor as well as the drugs dispensed to each patient on the occasion of each visit. The upper label from each of the weekly cartons dispensed to each patient was detached and fixed in the appropriate space in the CRF. On the same occasion, cartons of the previous supply were returned by the patient and remaining capsules were counted (and the resulting figure reported in the CRF) to estimate compliance. These used cartons were returned to the study monitors during site visits. All unused medication was to be returned to the Sponsor at the end of the study.

3.5 Efficacy and Safety Variables

At screening, a full medical history and physical examination (including ophthalmologic examination, chest X-ray and ECG) were carried out including a measurement of vital signs and laboratory tests. Patients were classified according to the DSM-III-R classification [9], and the severity of depression was quantified using the HAMD scale [11]. Patients were also assessed by the Composite Diagnostic Evaluation of Depressive Disorders (CODE-DD) [10], a psychiatric composite diagnostic system, the results of which are reported separately in an 'ad hoc' report.

3.5.1 EFFICACY

Patients were classified according to the CODE-DD at screening, on Day 42 (Week 6), after 6 and 12 months of treatment and/or at the time of withdrawal.

Patients were seen at regular intervals throughout the study and the following efficacy assessments carried out at the specified intervals. All psychiatric evaluations and ratings were to be carried out by the same observer for a given patient and in the same setting and at the same time of day if possible.

3.5.1.1 Hamilton Depression Rating Scale

The severity of depression was measured using the HAMD at screening, Days 0, 7, 14, 21, 28, 35, 42 and every two weeks during double-blind phase study.

The HAMD scale contained 21 items, each of which was scored (0-2, 0-3 or 0-4) to reflect whether the symptom was absent, trivial, mild, moderate or severe. Some of the items were more heavily weighted than others. The scores for all the symptoms were added together to give a global judgement of the severity of the depression.

The 21-item list of the HAMD used in this study is as follows:

<u>Item</u>	<u>Score range</u>	<u>Factor</u>
1. Depressed mood	(0-4)	V
2. Feelings of guilt	(0-4)	III
3. Suicide	(0-4)	III
4. Insomnia early	(0-2)	VI
5. Insomnia middle	(0-2)	VI
6. Insomnia late	(0-2)	VI
7. Work and activities	(0-4)	V
8. Retardation	(0-4)	V
9. Agitation	(0-4)	III
10. Anxiety (psychic)	(0-4)	I
11. Anxiety (somatic)	(0-4)	I
12. Somatic symptoms gastrointestinal	(0-2)	I
13. Somatic symptoms general	(0-2)	I
14. Genital symptoms	(0-2)	V
15. Hypochondriasis	(0-4)	I
16. Loss of weight	(0-2)	II
17. Insight	(0-2)	I
18. Diurnal variation	(0-2)	IV
19. Depersonalization and Derealization	(0-4)	III
20. Paranoid symptoms	(0-3)	III
21. Obsessional symptoms	(0-2)	III

More detailed definitions of the items included in the scale can be found in Enclosure 4 of Appendix 12.1.1

Pharmacia

Document 9550077

Factorialisation was carried out according to the ECDEU manual [12], to yield six factors: anxiety/somatisation (I), weight (II), cognitive disturbances (III), diurnal variation (IV), retardation (V) and sleep disturbances (VI).

3.5.1.2 Clinical Global Impression

The Clinical Global Impression (severity of illness, global improvement and efficacy index) was administered according to the ECDEU manual [12]. Severity of illness was assessed by the investigator at Days 0, 7, 14, 21, 28, 35, 42 and every two weeks during the double-blind treatment period. The following scale was used:

- 1 = normal, not at all ill
- 2 = borderline mentally ill
- 3 = mildly ill
- 4 = moderately ill
- 5 = markedly ill
- 6 = severely ill
- 7 = among the most extremely ill patients

In addition, the investigator evaluated the global improvement at each visit, with reference to the baseline assessment, according to the following scale:

- 1 = very much improved
- 2 = much improved
- 3 = minimally improved
- 4 = no change
- 5 = minimally worse
- 6 = much worse
- 7 = very much worse

An Efficacy Index was then assessed in accordance with the degree of improvement of a patient and the disability deriving from the side effects experienced. Details of the CGI and its Efficacy Index can be found in Enclosure 5 of Appendix 12.1.1.

3.5.1.3 Montgomery and Asberg Depression Rating Scale

The MADRS [13] was measured at Days 0, 7, 14, 21, 28, 35, 42 and at monthly intervals thereafter.

This scale consists of ten items relating to depression selected from the 67 items in the Comprehensive Psychopathological Rating Scale [14] in view of their sensitivity to change [13]. The ten items are as follows:

1. Reported sadness
2. Inner tension
3. Apparent sadness
4. Suicidal thoughts
5. Inertia
6. Inability to feel
7. Pessimistic thoughts
8. Concentration difficulties
9. Reduced sleep
10. Reduced appetite

The scale requires a structured interview for completion. A score of 0 to 3 for each item was used, as in reference 14. More detailed definitions of the items included in the scale can be found in Enclosure 6 of Appendix 12.1.1.

3.5.1.4 Zung Self-Rating Depression Scale

The Zung SDS [15] was measured at Days 0, 7, 14, 21, 28, 35, 42 and at monthly intervals thereafter.

The scale consisted of 20 statements which patients were asked to choose the appropriate answer for out of the following:

- None or a little of the time
- Some of the time
- A good part of the time
- Most or all of the time

A score of between 0-4 or 4-0, depending on the statements, was awarded to the answers and the score for all the answers was totaled in order to give the Zung SDS score. The 20 statements used are shown in Enclosure 7 of Appendix 12.1.1

Pharmacia

Document 9550077

3.5.2 SAFETY

3.5.2.1 Adverse Events

Spontaneously Reported

Patients were notified of any possible adverse events they might experience and were instructed to report any such adverse event to the investigators immediately.

The occurrence of adverse events was recorded at Day 0, 7, 14, 21, 28, 35, 42 and every two week thereafter.

Any adverse event, noticed by the investigators or reported by the patients was reported, regardless of presumed relationship to the study medication, in the appropriate section of the CRF (Adverse Event Report Form - Enclosure 8 of Appendix 12.1.1).

For each adverse event, the following information was entered the CRF: description, date of onset, date of stopping, severity, drug cause-effect relationship, outcome, effect of withdrawal of treatment and rechallenge. The investigators also had to note if the double-blind code had been broken, the action taken regarding the test drug (none, dose reduced or discontinued) and any treatment given as a result of the adverse event.

Severity was coded as follows:

- 1 = mild - awareness of sign or symptom, but easily tolerated
- 2 = moderate - discomfort enough to cause interference with usual activity
- 3 = severe - incapacitating with inability to work or due usual activity
- 4 = unknown

Relationship to test drug was coded by the physician as definite, probable, possible, doubtful, unknown or not related, according to Karch and Lasagna modified criteria as shown in Enclosure 9 of Appendix 12.1.1.

All serious* and/or unexpected** adverse events had to be reported to study monitors in the Sponsor subsidiary immediately (within 24 hours), and the details recorded on an Adverse Event Report Form. Serious adverse event was defined as any experience that was (potentially) fatal or life-threatening, disabling, incapacitating, requiring inpatient hospitalisation, causing a congenital anomaly or cancer, or due to an overdose.

* Code of Federal Regulation, Vol 21, Part 312. Revised as of April 1 1987, page 75.

** Bem JL, Breckenridge AM, Mann RD, Rawlins MD. Review of yellow cards (1986): report to the Committee on the Safety of Medicines. Br J Clin Pharmac 1988; 26: 679-690.

Unexpected Adverse Event

Unexpected adverse event was defined as any adverse experience that was not identified in nature, severity or frequency in the current Investigator's brochure for the study.

The same procedure applied for all patients who died during the course of the study or within 30 days of completion, irrespective of whether the event was judged as related to treatment. If an autopsy was performed, a copy of the pathological report was to be sent to the Sponsor.

Adverse Events Reported Through a Check-List

The presence or absence of selected adverse events was solicited through a check list especially designed for the identifying events frequently reported in patients on antidepressant medication. These events could be either reported by the patient or observed by the investigator.

For each adverse event, the same procedure as for spontaneously reported adverse events was followed in terms of recording of information in the CRF (Adverse Event Report Form) and reporting of the 'serious' or 'unexpected' adverse event to the Sponsor.

3.5.2.2 Clinical and Laboratory Tests

Vital Signs

Blood pressure and heart rate (supine and standing) were measured at screening, on Days 0, 7, 14, 21, 28, 35, 42 and every two weeks thereafter.

Supine blood pressure and heart rate were measured in the morning after 5 minutes in the supine position and standing blood pressure and heart rate were measured 1 to 2 minutes after standing up.

ECG

An ECG was recorded at screening, on Days 14, 28, 42 and every two months in the double-blind period of the trial.

Ophthalmological examination

A standard ophthalmological examination, including assessment of visual acuity, colour vision, intraocular pressure, visual field, slit lamp examination of lens and cornea, and dilated fundus examination was performed at screening and the end of the double-blind period of the trial.

Laboratory Tests

Laboratory tests were recorded at screening, on Days 14, 28, 42 and every two months in the double-blind period of the trial.

Pharmacia

Document 9550077

The laboratory tests comprised the following: full blood count, serum electrolytes, liver enzymes, blood sugar, serum alkaline phosphatase, blood urea nitrogen (BUN), serum creatinine, uric acid, total and direct bilirubin, total serum protein and electrophoresis, serum cholesterol and triglycerides, rT₃, T₃ and T₄ (at screening only), and urinalysis.

Laboratory tests were also measured for patients who withdrew prematurely because of a serious adverse event.

3.7 GCP Compliance and Data Quality Assurance

The study was initiated before the formal adoption of Good Clinical Practice guidelines by European Regulatory Authorities and in the absence of Company Standard Operating Procedures. However, operating procedures for study monitoring and co-ordination were defined and are described in Attachment A of Appendix 12.1.1.

Training on diagnostic assessment was carried out during the first investigator meeting and during the site visit performed by the Scientific Co-ordinator of the study. Inter-rater reliability sessions on the instrument used for the assessment of change, particularly on the HAMD, were carried out during monitoring visits for training purposes by employing four videotaped interviews.

During the monitoring visits, which were made at regular intervals, the monitor validated the content of the CRF against source documents on the basis of the agreed procedures.

Site, trial master file and report audits were carried out by the Company Quality Assurance Unit.

3.8 Statistical Analysis

3.8.1 POWER CONSIDERATIONS

The main evaluation of treatment effectiveness was based on the comparison of the proportion of patients experiencing relapse (see below for definition) during the double-blind phase in each of the two treatment arms (reboxetine and placebo) out of the number of randomised patients.

In agreement with this goal, the following system of hypotheses was set up:

$$H_0: \pi_{RBX} \geq \pi_{PLC}$$

$$H_a: \pi_{RBX} < \pi_{PLC}$$

where π_{RBX} and π_{PLC} are the true relapse rates in the reboxetine and the placebo treated population, respectively.

Given the fact that a 15% difference in relapse rate was considered as a clinically relevant difference and assuming that 50% of placebo-treated patients were expected to relapse within one year, 135 patients in each arm were required to reject the null hypothesis at a one-tail α -level = 0.05 and with a power $(1 - \beta) = 0.80$ for the alternative hypothesis of a difference ($\delta = \pi_{PLC} - \pi_{RBX}$) as high as, or higher than, 15%.

Taking into account that 20% of the patients entering the run-in phase could not have achieved the response at the end of this phase, 358 patients were to be recruited.

3.8.2 PLANNED ANALYSIS

The main comparison was to be carried out on the basis of the rate of relapse (% of randomised patients experiencing relapse (as defined in Section 3.8.3.2)) using a test based on binomial distribution. The relapse time within each treatment group was to be estimated by the Kaplan-Meier method and compared by the log-rank test.

In addition, the remission rate (% of randomised patients experiencing remission at the last assessment and at the end of the 1-year treatment period) was to be compared between the two treatment groups.

The frequency of patients showing a clinically relevant decrease (≥ 20 mmHg) in standing systolic blood pressure was to be compared between the two groups.

Adverse events were to be presented by listing, patient-by-patient, all events and the cumulative frequencies of occurrence by treatment. If there were clinically significant differences in the occurrence of adverse events between treatment groups, these were to be compared.

Laboratory data was to be classified as normal or abnormal according to the normal ranges of the performing laboratory and the frequency of the abnormal results after treatment compared between the two treatment groups.

3.8.3 ANALYSIS CARRIED OUT

3.8.3.1 Baseline Comparability of Treatment Groups

Baseline characteristics (e.g. age, diagnosis, age at onset, number of previous episodes) which might have influenced the main end-point of the study were summarised considering both all the patients entered into the run-in phase and only the patients subsequently randomised either to reboxetine or placebo in the double-blind phase. In this latter presentation, patients were grouped according to the treatment they were allocated to afterwards, in order to verify the comparability of the two treatment groups.

3.8.3.2 Efficacy Analyses

Efficacy Criteria

The following definition and selection applies to the set of data analysed at the end of open phase:

- | | |
|------------|---|
| Remission: | HAMD total score lower than or equal to 10 (absolute value). |
| Response: | HAMD total score decrease equal to or greater than 50% compared to the baseline value (Visit 0). According to this definition, and based on the inclusion criterion which required a total score of HAMD at entry of at least 18, not all patients who achieved remission (as defined above), were included in the broader category of response ($18 \cdot 0.5 = 9$). |

Pharmacia

Document 9550077

The following definition and selection applies to the set of data analysed during double-blind phase:

- Relapse:** Increase in HAMD total score equal to or greater than 50% compared with the value at randomisation (Visit 6) and HAMD total score equal to or greater than 18 (absolute value).
- Time to relapse:** Number of days elapsing between the randomisation date (Visit 6) and the date when the patient was first classified as "relapse" according to the above definition.
- Time to censoring:** Number of days elapsing between randomisation (Visit 6) and withdrawal from the study for reasons other than occurrence of relapse or deterioration requiring study treatment discontinuation (classified in the end-of-treatment summary as deterioration).
- Time to treatment failure:** Number of days elapsing between randomization date (visit 6) and date of relapse or of withdrawal from the study for any reason other than improvement.
- Maintenance of the response:** Cumulative probability of the long lasting effect of the treatment based on the time to treatment failure.

Double-blind Phase

Patients who entered the double-blind phase of the study but who did not fulfil the criterion of response were excluded from efficacy analysis.

The primary analysis of treatment efficacy (main end-point) was based on the comparison of the proportion of patients experiencing at least one relapse in the long-term treatment period following randomisation, out of the total number of randomised patients, in each of the two treatment groups. In this analysis, patients withdrawing for any reason were classified according to whether or not they had relapsed during the observation period. A chi-square test [16] was applied in order to test the null hypothesis.

The cumulative probabilities of relapsing in the two treatment groups were described by the Kaplan-Meier method and compared by the log-rank test [17].

The same analysis was carried out for the sub-group of patients in remission at the end of the initial 6 weeks of treatment.

In both analyses, patients withdrawn for any reason were considered censored at the time of withdrawal. In order to ensure that the censoring patterns in the two treatment groups were comparable and independent of the treatment, the Kaplan-Meier curves of time to censoring were provided.

The crude rate of patients who did not relapse at least once and who did not withdraw (unless because of improvement) during the first six and the following six months of the double-blind period, respectively, were compared between the two treatment groups by chi-square test, in order to test the maintenance of the response achieved in the open phase in the two periods separately. The denominator of the analysis in the last six months includes all the patients who did not relapse or withdraw in the preceding six months. In addition, maintenance of the response including both the total observation period of 52 weeks and the first 6 months after randomisation (up to week 26) in the two groups was described according to the Kaplan-Meier method and between-treatment difference was tested by the log-rank test.

As planned in the protocol, the remission rate at the last assessment of the double-blind phase was calculated and the between-treatment difference tested (chi-square test).

Moreover, the total scores for HAMD, MADRS, Zung SDS, and CGI variables have been summarised by descriptive statistics at each visit and considering the last valid observation, in the two treatment groups.

3.8.3.3 Safety Analyses

All the analyses were carried out on two sets of data, according to the study design. The first set refers to the run-in phase and includes all the patients entered into the study, while the second set includes only the randomised patients and considers the assessments performed during both run-in and double-blind period, in order to give an overview of the safety of the whole study period (randomised patients who did not receive any dose in the double-blind phase have been excluded). In both cases, the values collected before the start of run-in phase were considered as reference values for the comparison vs baseline.

Vital Signs

Vital signs as measured at each assessment time were summarised by descriptive statistics. Patients with orthostatic hypotension (a decrease > 20 mmHg of the systolic blood pressure from lying to standing) were described. Finally, the frequency of patients showing clinically relevant changes ($\geq 20\%$ or more vs baseline) or such a modification accompanied by absolute critical values (≥ 160 or ≤ 100 mmHg for systolic blood pressure; ≥ 100 or ≤ 70 mmHg for diastolic blood pressure; ≥ 100 or ≤ 50 beats/min for heart rate) at each evaluation time were tabulated.

ECG

ECG results have been summarised in frequency tables showing normal/abnormal findings at each visit. Changes from baseline (i.e. normal to abnormal and vice versa, or changes in type of abnormality) have been displayed.

Pharmacia

Document 9550077

Laboratory Examinations

For all the laboratory examinations and within each of the two treatment groups, the following analyses have been provided:

- frequency and percentage of patients whose values were below, within or above the normal range at baseline and shifted to values below, within or above the normal ranges at each visit. Either the MacNemar test or Stuart Maxwell test [18] has been applied in order to test if the distribution across categories at baseline differs from the distribution at each visit.
- continuous values of laboratory tests were standardized according to the method proposed by Chuang-Stein [19], using as reference values the one reported in the Cecil Textbook of Medicine [20]; the Wilcoxon Rank Signed test for paired data [21] was applied in order to compare the values during treatment with those recorded at baseline.

The usage of statistical tests in this framework aimed mainly at providing screening tools for selecting relevant changes within each single examination, which were to be considered clinically relevant on the basis of the concordance with other examinations evaluating the same organ function. As an arbitrary pragmatic criterion statistical significance was claimed when p value was lower than 0.01.

Moreover, abnormal values of laboratory tests defined as clinically relevant by pre-defined criteria (Appendix 12.1.8) were specially considered and frequencies of clinically relevant abnormalities calculated.

Adverse Events

In the analysis of adverse events, attention has been focused on treatment-emergent signs and symptoms, i.e. events that were not present at baseline that appeared during treatment or, if present at baseline, that became more severe during treatment. The analyses were essentially descriptive and, for each set of patients (see above) and each treatment group, they were performed both in terms of the number of patients complaining of adverse events and the number of events.

Each event has been classified as occurring during the run-in phase or the double-blind phase depending on its onset. In the assessment of the frequency of patients with adverse events, each patient was counted once in any given phase, provided that he/she complained of one or more events occurring during that phase. The analyses were performed taking into account the occurrence of at least one sign or symptom, the occurrence of at least one event for each body system and, in detail, the occurrence of each type of sign or symptom. When severity of the events was considered, the worst reported degree was selected. In order to explore possible differences, patients were also classified by sex and age.

The cumulative risk of developing the first adverse event during the treatment period was estimated by the Kaplan-Meier method (open phase only). Furthermore, the weekly (run-in phase) or monthly (double-blind phase) frequency of patients presenting adverse events (either because of the onset of new events or because of the persistence of those previously developed) was assessed.

The events have been described by frequency tables according to duration, onset time, symptomatic treatment, relationship to study medication, study drug adjustment and outcome. The duration of any event was computed as the number of days from its onset up to its recovery or, in the absence of a recovery date, up to the last reporting date (approximate duration).

3.9 Data Management

Data management was carried out in the Biometrics and Data Management Department of Pharmacia, Milan.

CRFs data were entered into an IBM 3090 computer (according to the arrival flow) through data entry masks generated by SAS FSP release 6.06 and 6.07.

ECG tracings were classified and subsequently grouped according to the codes reported in Appendix 12.1.9. Previous and concomitant diseases were coded according to ICD9 dictionary [22]; concomitant drugs were coded according to the Drug Reference List [23]; and adverse events according to the WHO-ART dictionary [24]. In the absence of an adequate code and preferred term, "urinary hesitancy" was coded as "micturition disorder", and "blurred vision" as "vision abnormal". The mentioned events therefore appear in the tables under the indicated terms.

Subsequently, data were scrubbed by an electronic procedure set up to this purpose which generates listings of discrepancies between the actual value entered and pre-defined algorithms. Computer programs generated for this purpose are archived in the Biometrics and Data Management Department. These listings were reviewed by clinical personnel and editing of CRFs was requested at the Investigator site, whenever appropriate. Corrections were entered, repeating the loop until the files were completely clean.

Reporting, as well as statistical analyses, were carried out with SAS PROCs (version 6.07), apart from the Stuart-Maxwell test. The programs relevant to the latter are appended in Appendix 12.1.10. A selection of statistical analyses outputs is shown in Appendix 12.1.11.

4. STUDY PATIENTS

4.1 Disposition of Patients

Three hundred and fifty-eight patients were recruited to the open phase of this study at nine centres. Recruitment by centre is shown in Table 1. Centre numbers 1 and 10 recruited the majority of the patients, 41.9% and 21.2% respectively, while patient inclusion was minimal in centre numbers 2 (4 patients), 3 (10 patients), and 8 (7 patients). The remaining centres admitted 20-38 patients each to the study. Patient disposition is summarised in Table 2. A total of 322 patients (89.9%) completed the open phase of the study in accordance with the protocol and 36 patients (10.1%) withdrew. The main reasons for withdrawal are shown in Table 3.

One patient committed suicide. The narrative summary of the event is enclosed (Appendix 12.2.1); 13 patients (3.6% of the population admitted) dropped out due to adverse events (see Section 8.2.3.2); deterioration and unco-operativeness caused discontinuation in 10 and 11 cases, respectively (approximately 3% of the admitted patients).

Two hundred and eighty-six patients from 8 centres were randomised to treatment with either reboxetine (145) or placebo (141) as shown in Table 4. Three patients (centre 10: no. 36/36, 83/60, 18/283) were randomised to treatment with either reboxetine (2 cases) or placebo (1 case) but never received it. They were excluded from the analysis.

The frequency and timing of withdrawals, according to protocol provisions or for other reasons, during the double-blind phase is indicated by reason in Table 5.

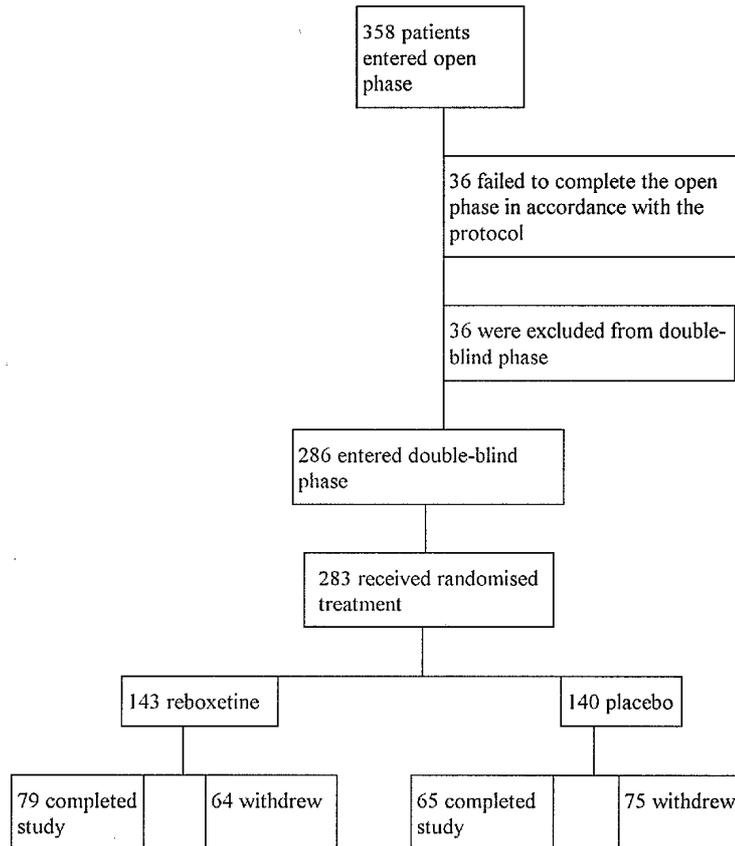

Lack of efficacy was given as a reason for withdrawal twice as often by placebo recipients (36 patients, 25.7% of the randomised and treated cases) compared with reboxetine recipients (17 patients, 11.9%). Adverse events were associated with withdrawal in six patients under reboxetine (4.2% of the randomised and treated patients) and two patients under placebo (1.4%). In total, 64 patients (44.8% of the randomised and treated cases) discontinued the double-blind treatment in the reboxetine group and 75 (53.6% of the randomised and treated cases) in the placebo group. Discontinuations were mainly apparent within the seventh months of treatment.

Pharmacia

Document 9550077

The overall picture of patient disposition is shown below.

Disposition of patients

4.2 Protocol Deviations

4.2.1 COMPLIANCE WITH ENTRY CRITERIA

The frequency of non-compliance with inclusion/exclusion criteria of relevance for inferential purposes is given in Table 6. The most frequent reason (8.7% of the patients) for possible non-compliance with the exclusion criteria was related to abnormalities of thyroid function tests, suggestive of possible underlying, undiagnosed, endocrine disorder. Psychotropic medication with a possible influence on baseline assessments that was not allowed was administered during the wash-out period in 2.5% of the patients.

4.2.2 CONCOMITANT MEDICATIONS

The frequency of administration of concomitant drugs not allowed by the protocol due to their psychotropic properties during the open and double-blind phase is given in Table 7. This refers mainly to long-acting benzodiazepines, rarely administered and with similar frequency in the placebo and reboxetine groups.

4.2.3 RESPONSE CRITERION (HAMD TOTAL SCORE DECREASED BY 50% OR MORE) FOR ADMISSION TO DOUBLE-BLIND PHASE

The frequency of non-compliance with the response criterion is given in Table 8. As already mentioned, this applied to 18 cases, 10 randomised to reboxetine and 8 to placebo. All but two cases were improved in comparison with baseline, the improvement being superior to 40% in seven cases. As mentioned, these patients were excluded from efficacy analyses.

4.2.4 RANDOMISATION

Distribution and use of study medication were to be done, as previously mentioned, in blocks of 4 treatments, used in sequence from the smallest to the highest number according to patient temporal entry into the study; each centre was supposed to receive and use only complete blocks. In order to provide a discrepancy log with respect to the randomisation sequence, patients were listed according to their study entry date and the treatment foreseen to be assigned according to the random sequence of the blocks available at the center was matched by a sequential criterion. Mismatching between the foreseen treatment and the treatment actually received was identified as a randomisation error.

As reported in Table 9, errors in randomisation led to administration of the alternative experimental treatment in 49 patients (17.3%), but the within-centre error rate was highly variable (0-50%). However, as shown in Table 10, this randomisation error was evenly distributed in the reboxetine and the placebo groups (24 and 25 cases, respectively). In addition, in eight cases, four per group, problems in material supply led to utilization of the

Pharmacia

Document 9550077

material left by drop-out cases, which was therefore “out of randomisation” and they were analysed as for the actual treatment received.

4.2.5 ASSESSMENT INTERVALS

The summary statistics of the efficacy and safety assessment intervals are shown in Table 11. The range of days from treatment start indicates little, if any, deviation from the protocol time-schedule for the majority of assessment intervals.

4.2.6 WITHDRAWALS FOR PROTOCOL VIOLATION

Ten patients (6 reboxetine, 4 placebo) were withdrawn from the double-blind phase of the study because of protocol deviations as shown overleaf:

Protocol Deviations Causing Withdrawal from the Double-blind Phase of the Study

Protocol deviation	Reboxetine	Placebo	Total
Anxiolytic intake	2	1	3
Pregnancy	1	0	1
Misuse of study medication supply	3	1	4
Other	0	2	2
Total	6	4	10

4.3 Demographic Data

Demographic data of the whole sample admitted to the open phase and of the two subsamples subsequently randomised to reboxetine and placebo treatments for the double-blind phase of the study are given in Table 12 and 13 respectively and are presented below:

Summary of Demographic Data

		Open phase Reboxetine		Double-blind phase			
		n	(%)	Reboxetine		Placebo	
		n	(%)	n	(%)	n	(%)
Sex	female	263	73.5	115	79.3	95	67.4
	male	95	26.5	30	20.7	46	32.6
Total		358	100	145	100	141	100
		Mean	SD	Mean	SD	Mean	SD
Age (years)		43.2	11.8	43.4	11.6	42.3	12.2
Height (cm)		165.6	8.4	165.3	7.5	165.4	8.9
Weight (kg)		66.7	13.0	67.2	13.4	66.0	11.8

Female patients were prevalent in both treatment groups, and particularly so in the reboxetine group. The reboxetine and placebo treatment groups were well matched for age, height and weight.

4.3.1 SEVERITY OF DEPRESSION

The severity of depression, according to the HAMD, CGI and MADRS scales, at entry and at the different time intervals during the open phase of the study, is described in Tables 25, 29 and 35. As shown below, the severity of depression at entry in the total population was similar to the one of randomised patients and, among randomised patients, there was no important difference between the treatment groups at Day 0.

Pharmacia

Document 9550077

Severity of Depression at Day 0 in all patients

	n	Mean	SD
HAMD	358	29.6	5.6
MADRS	358	18.4	4.1

	n	(%)
CGI severity		
Normal	0	
Borderline mentally ill	0	
Mildly ill	3	(0.8)
Moderately ill	30	(8.4)
Markedly ill	223	(62.3)
Severely ill	87	(24.3)
Extremely ill	15	(4.2)

Pharmacia

Document 9550077

Severity of Depression at Day 0 in Randomised Patients

	Reboxetine			Placebo		
	n	Mean	SD	n	Mean	SD
HAMD	145	29.1	5.5	141	29.7	5.7
MADRS	145	17.9	4.0	141	18.6	4.2
	n	(%)		n	(%)	
CGI severity						
Normal	0			0		
Borderline mentally ill	0			0		
Mildly ill	1	(0.7)		1	(0.7)	
Moderately ill	12	(8.3)		13	(9.2)	
Markedly ill	89	(61.4)		91	(64.5)	
Severely ill	37	(25.2)		32	(22.7)	
Extremely ill	6	(4.2)		4	(2.8)	

4.3.2 PREVIOUS HISTORY OF DEPRESSION

Frequency of DSMIII-R diagnostic classifications and summary statistics (including mean with SD as well as median values with range) of features of the history of the mental disorder in the total population and in the randomised patients are shown in Tables 14 and 15 respectively.

The median age at onset of the depressive disorder, the median number of previous episodes of depression, the median duration of the last episode and the median duration of the present episode in the total population and in the randomised patients at entry are presented for each treatment group in the following table:

Previous History of Depression in the Total Population and in Randomised Patients

	All patients			Reboxetine			Placebo		
	n	Median	(range)	n	Median	(range)	n	Median	(range)
Age at onset (years)	356	34	(11-63)	145	34	(13-60)	139	32	(11-62)
Number of previous episodes	356	3	(1-15)	145	3	(1-15)	139	3	(1-10)
Duration of the last episode (weeks)	354	24	(2-364)	143	24	(3-364)	139	24	(2-364)
Duration of the present episode (weeks)	354	8	(0.1-364)	144	8	(0.1-364)	139	10	(0.6-208)

The treatment groups were well matched and similar to the admitted population for all aspects.

The frequency of previous antidepressant therapy by active principle is described in Table 16. As expected, tricyclic antidepressants were the most frequently prescribed and were similarly represented in the reboxetine and placebo groups.

4.3.3 MEDICAL HISTORY

Medical history in the total population and in the two groups of patients randomised to reboxetine and placebo is given in Table 17 and summarized by body system in Table 18. Worth noting is the slightly higher frequency of diseases of the circulatory system in the reboxetine group.

5. STUDY MEDICATION AND COMPLIANCE

The frequency of each dose of the experimental treatment administered in each study day is given in Tables 19 (open phase), 20 and 21 (double-blind phase, reboxetine and placebo, respectively). The per protocol dose was reportedly administered to almost all patients during the whole treatment period. The few exceptions mainly concerned instances of decrease of the daily dose or temporary treatment interruption in a maximum of 7 patients per treatment day during the open phase and of 2 and 3 patients in the reboxetine- and placebo-treated patients, respectively, during the double blind phase.

Comparison of the administered dose, as reported in the compliance section of the CRF, with the expected dose, as indicated in the experimental treatment section of the CRF, allowed calculation of the compliance with the treatment regimen; full compliance was defined in the case of correspondence between the dose prescribed (the per protocol one or a lower one prescribed by the physician, e.g. in case of adverse events) and the dose reportedly taken. A global compliance over the treatment period was calculated and patients were classified accordingly, as reported in Table 22. In 99% of the cases during the open phase and in 97 and 98% of the reboxetine- and placebo-treated cases during the double-blind phase, the reported compliance was 100%.

6. CONCOMITANT MEDICATION

The frequency of patients receiving a concomitant medication at least once is indicated by active principle in Table 23 (open phase) and 24 (double-blind phase). Most frequently newly administered was chloral hydrate as sleep inducer. In addition to the psychotropic medications not allowed by protocol administered in few cases in both treatment groups, already commented in Section 4.2.2, other drugs were only seldom administered, generally following the emergence of adverse events, with no major differences in frequency of administration between reboxetine and placebo.

7. EFFICACY RESULTS

7.1 Open Phase of the Study

7.1.1 HAMILTON DEPRESSION RATING SCALE

Summary statistics of total HAMD scores at each visit in the observed cases are shown in Table 25 and for individual HAMD factors in Table 26. The last assessment of the open phase is summarised in Table 27.

At the last assessment, the mean total HAMD score was reduced from 29.6 at baseline to 12.9. Among HAMD factors, the median of the differences vs baseline indicates maximal improvement for the factors 'retardation' (1.5 points), 'diurnal variation' and 'anxiety/somatisation' (1 point), corresponding to those most severely effected at baseline.

Pharmacia

Document 9550077

As summarised in Table 28, a total of 272 patients (76.0% of the admitted) were responders at Week 6 and of them 179 patients (50.0% of the admitted) were seen to be in remission.

7.1.2 CLINICAL GLOBAL IMPRESSION

7.1.2.1 Severity of Illness

The distribution of the CGI severity scores at each visit of the open phase in the observed cases is presented in Table 29, while the distribution of the scores at last assessment is summarised in Table 30. A clear-cut modification of the overall picture is apparent, with the majority of the patients being markedly to severely ill at baseline (90.8%) and normal to mildly ill at last assessment (69.8%).

The shift table of the last value vs Day 0 (Table 31) showed that the majority of patients had the severity of illness decreased (87.7%) and only 2.0% increased.

7.1.2.2 Global Improvement

The distribution of the CGI global improvement scores at each visit of the open phase in the observed cases are shown in Table 32. The last assessment of CGI improvement during the open phase of the study is summarised in Table 33.

The proportion of patients who were 'very much improved' increased from 0.8% at Week 1 to 50.5% at Week 6 and patients who were 'much improved' increased from 10.3% at Week 1 to 33.4% at Week 6. At the last assessment the majority of patients was classified as significantly improved, either very much (45.8%) or much (31.3%).

7.1.2.3 Efficacy Index

Summary statistics of the efficacy index, which attempts to weigh up the therapeutic benefit i.e. therapeutic effect vs side effects, are shown in Table 34. The mean and median efficacy index indicate a therapeutic effect outweighing side effects (1.5 or above) from Week 2 onwards.

7.1.3 MONTGOMERY-ASBERG DEPRESSION RATING SCALE

Summary statistics of MADRS total scores at each visit in the observed cases and at last assessment are shown in Table 35 and 36, respectively. The average MADRS total score was reduced from 18.4 at baseline to 7.8 at the last assessment.

7.1.4 ZUNG SELF-RATING DEPRESSION SCALE

Summary statistics of the Zung SDS total scores at each visit in the observed cases and at the last assessment are given in Tables 37 and 38, respectively. Complete data were obtained at baseline and at least one visit in only 317 of the 358 admitted patients. In this

subset of cases, the average Zung SDS total score was reduced from 57.1 at baseline to 41.3 at the last assessment.

7.2 Double-blind Phase

As mentioned, efficacy results have been analysed and are presented at each visit during the open and double-blind phases of the study for those patients who received randomised treatment, after exclusion of the 18 patients (10 of the reboxetine and 8 of the placebo group) admitted to randomised treatment while not complying with admission response criteria.

7.2.1 HAMILTON DEPRESSION RATING SCALE

7.2.1.1 HAMD Total Score

Summary statistics of total HAMD scores at each visit are shown in Table 39 for the reboxetine group and in Table 40 for the placebo group. Summary statistics of the HAMD total scores at the last assessment in the two treatment groups are given in Table 41.

In the 133 responder patients subsequently randomised to reboxetine, the mean HAMD total score was reduced from 29.2 at Week 0 to 8.8 at Week 6. This improvement was slightly increased in the patients continuing to receive the experimental treatment, with an average score of 5.9 at Week 52 in the 76 assessed patients still on treatment. The mean HAMD total score in the 132 responder patients subsequently randomised to placebo was reduced from 30.1 at Week 0 to 9.1 at Week 6, i.e. similarly to the above. This improvement was maintained in the patients continuing to receive the experimental treatment, a marginal deterioration being apparent in the 62 assessed patients still on treatment at Week 52 (11.1 points). Last assessment mean HAMD scores were 7.9 and 13.9 in reboxetine and placebo arm respectively. This unbiased comparison confirmed the difference between the two treatments.

Study End-Points

The number of randomised responder patients who relapsed at least once is shown by treatment group in Table 42. Among the 133 responder patients randomised to reboxetine, 21.8% fulfilled the criterion for relapse at least once during the study, while 56.1% of the 132 responder patients randomised to placebo did, the between-treatment difference being highly significant ($p < 0.001$).

The pattern of the time to relapse according to the Kaplan-Meier method in the two treatment groups is shown in Figure 1. The cumulative risk of relapse is clinically and statistically significantly higher under placebo than under reboxetine ($p = 0.0001$); under reboxetine, the relapses mainly occur within the first 3-4 months of follow-up, while under placebo, the cumulative probability of relapse increases almost steadily up to the end of the observation period.

In order to exclude the influence of the missed observations, due to possible differences between the two groups in drop-out rate, on the above findings, the censoring pattern was calculated, and is reported in Figure 2. No difference between the two groups is apparent.

When the results are considered in terms of maintenance of the response (defined as absence of relapse or relapse-free) (Figure 3), the cumulative probability is clinically and statistically significantly higher under reboxetine than under placebo ($p=0.0001$).

A further analysis was carried out that tested separately the differences between the two groups in the proportion of relapse-free patients during the first six months and the last six months of the study. As shown in Table 43, again a clinically and statistically significant difference between the two groups is apparent in both treatment periods ($p\leq 0.001$), with 60.9 vs 40.2% of the patients being relapse-free under reboxetine and placebo respectively in the initial six months and 88.0 vs 59.2% of the reboxetine- and placebo-treated patients who entered the last six months of treatment being relapse-free at all available observations.

In addition, the time pattern of relapse was described according to the Kaplan-Meier method on the subset of patients in remission at the end of the open phase (Figure 4). In this subset of patients, the rate of relapse was lower than in responder patients in both treatment groups, but particularly so in the initial three months after randomisation in the placebo group. In any case, the between-treatment difference was again highly significant ($p<0.001$).

The number of randomised responder patients in remission at the last assessment is shown by treatment group in Table 44; 78.2% of the reboxetine-treated patients and 44.7% of the placebo-treated patients were in remission at the last assessment, the between-treatment difference being highly significant ($p<0.001$).

7.2.1.2 HAMD Factors

Summary statistics of the HAMD factors in the responder patients randomised to reboxetine or placebo at the different assessment intervals in the observed cases are given in Tables 45 and 46, respectively. The pattern of the medians of the differences vs baseline indicates that the factors maximally improved in the first six weeks of open reboxetine treatment, i.e. retardation, diurnal variation and anxiety/somatisation. Retardation and anxiety/somatisation had a further marginal improvement in the patients continuing to receive reboxetine upon long-term treatment, but not in those receiving placebo.

In addition, sleep disturbances also appeared to be more clearly ameliorated in the patients continuing to receive reboxetine than in those under placebo medication.

7.2.2 CLINICAL GLOBAL IMPRESSION

7.2.2.1 Severity of Illness

The distribution of the CGI severity scores at each visit is given in Table 47 and the summary of last assessment values is presented in Table 48. The distributions of the scores at Week 6 were similar in the two groups, with 20.3 and 25.0% of the responder patients randomised to reboxetine and placebo, respectively, being judged normal, 39.1 and 34.8% borderline and 29.3 and 28.0 mildly ill. With continuation of treatment, the most clear-cut difference between the two groups is related to the proportion of patients classified as normal, relatively stable up to a maximum level of 33.9% in the placebo group and steadily increasing up to 73.7% at Week 52 in the reboxetine group. At the last assessment, 48.1% of the reboxetine-treated cases were judged normal, compared to 22.7% of the placebo-treated cases. A shift table of the last value vs Day 0 (Table 49) showed that the severity of illness under reboxetine had decreased in 95.5% of patients, increased in 2.3% of patients and remained the same for 2.3% of patients, whereas under placebo, severity of illness had decreased in 83.3% of patients, increased in 6.1% of patients and remained the same in 10.6% of patients.

7.2.2.2 Global Improvement

The distribution of CGI scores at the different weeks of treatment is shown by treatment group in Table 50 and the summary of last assessment values is given in Table 51. At Week 6 the proportion of much to very much improved patients was similar in the two groups. With continuation of treatment, the proportion of very much improved cases tended to remain stable (between 50 and 60%, 64.5% at Week 52) under placebo, while a progressive increase was apparent under reboxetine, up to a maximum of 94.7% at Week 52. At last assessment very much improved cases were 72.9 and 42.4% in the reboxetine and placebo groups, respectively.

7.2.2.3 Efficacy Index

Summary statistics of the efficacy index at each visit are shown in Table 52 and 53 for the reboxetine- and placebo-treated patients, respectively. No major differences between the two groups are apparent.

7.2.3 MONTGOMERY-ASBERG DEPRESSION RATING SCALE

Summary statistics of the total MADRS scores at each visit are shown in Table 54 and summarised for the last assessment in Table 55. The total MADRS score was reduced from 17.9 and 18.7 at Week 0 in the responder patients subsequently randomised to reboxetine and placebo, respectively, to 5.3 at Week 6 in both groups.

A further progressive improvement was apparent in the patients continuing to receive reboxetine, up to 3.1 on average in the 76 patients assessed at Week 52, while a slight

progressive deterioration was observed in the patients continuing to receive placebo, up to 7.0 on average in the 62 patients assessed at Week 52.

7.2.4 ZUNG SELF-RATING DEPRESSION SCALE

Summary statistics of the total Zung SDS scores at each visit are shown in Table 56 and summarized for the last assessment in Table 57. In the placebo and reboxetine groups 124 and 128 patients, respectively, had a complete assessment of the scale at their last assessment of the double-blind phase. Among these patients, 122 and 123, respectively, had a full assessment at Week 6. The total Zung SDS score was similar in the two treatment groups both at baseline (58.1 and 55.8 in the placebo and reboxetine group, respectively) and at Week 6 (38.8 and 36.3, respectively). A further progressive slight improvement was apparent in the patients continuing to receive reboxetine, up to 32.0 on average in the 75 patients with complete assessment at Week 52, while this was not the case in the patients continuing to receive placebo, with an average score of 40.6 points in the 58 patients with full assessment at Week 52.

7.3 Efficacy Conclusions

The planned analyses of the study end-points, i.e. frequency and rate of relapse, indicates that reboxetine is effective in the maintenance therapy of Major Depressive Disorders. These results are confirmed by the analysis of the secondary efficacy variables.

The additional analysis of the frequency of absence of relapse during the initial six months and subsequent six months of treatment indicates that reboxetine is effective in both situations, thus suggesting that the observed findings could be connected with prevention not only of relapse of the index episode, but also of recurrence of new episodes.

8. SAFETY RESULTS

8.1 Safety Population and Extent of Exposure

8.1.1 NUMBER OF PATIENTS IN SAFETY ANALYSIS

All the patients who received study treatment were included in the safety analysis, i.e. 358 patients in the open phase and 283 patients (143 reboxetine, 140 placebo) in the double-blind phase of the study.

8.1.2 TOTAL DRUG EXPOSURE

The number of patients exposed for six weeks, 2, 3, 6, 9 and 12 months is given in Table 58. Of the 358 patients entered, 285 were exposed to reboxetine at least for six

Pharmacia

Document 9550077

weeks, 124 at least for three months, 101 at least for 6 months, and 79 at least for 12 months.

8.2 Adverse Events

8.2.1 ANALYSIS OF ADVERSE EVENTS

8.2.1.1 Open Phase

The number of patients with adverse events and the number of adverse events during the open phase of the study are grouped by sex in Table 59 and by age classes in Table 60; 51.9% of the patients exposed had at least one, and an average of 2, adverse events; males suffered from adverse events more frequently (62.1%, 95% C.I. 51.6-71.9%) than females (48.3%, 95% C.I. 42.1-54.5%); patients 31 to 45 years old had adverse events more frequently, though not statistically significantly so, (59.0%, 95% C.I. 50.5-67.1%) than patients over 45 years (43.6%, 95% C.I. 35.7-51.7%).

Absolute and Per Cent Frequency

The absolute and percentage frequency of patients suffering from adverse events and of adverse events is grouped by event and sex in Tables 61 (all events) and 62 (aggregated by body system), and by body system and sex in Table 63. Most frequently reported were dry mouth (19.0% of the patients) and constipation (16.8%). Reported in 1 to 10% of the patients were increased sweating (8.1%), tachycardia and insomnia (6.1% each), micturition disorder (corresponding to urinary hesitancy, 5.6%), decreased libido (5.0%), dizziness (4.5%), abnormal vision (corresponding to blurred vision) and paresthesia (3.4 and 3.1%, respectively), tremor and headache (2.8 and 2.5%, respectively), and urinary retention (2.2%). The most relevant between-gender difference was related to the frequency of micturition disorders (urinary hesitancy) and urinary retention, complained of mainly by male patients (18.9 and 7.4% respectively) and of decreased libido, again complained of mainly by males (11.6%).

Most frequently affected, therefore, was the autonomic nervous system (26.5% of the patients, most frequently affected system in female patients with adverse events, 57.4%), and the gastro-intestinal (GI) system (18.7%). Psychiatric and cardiovascular (CV) disorders affected 12.6 and 10.9% of the patients, respectively, while central and peripheral nervous system (NS) and vision disorders appeared in 8.7 and 3.9% of the patients, respectively. Urinary system disorders affected 8.1% of the overall population, but 26.3% of male patients, and corresponded to the most frequently affected system in male patients with adverse events (42.3%).

Occurrence

The occurrence of adverse events is grouped by week of onset and event or body system in Tables 64 and 65, respectively. The cumulative risk of developing the first adverse event

64 (2598)

during treatment is described according to the Kaplan-Meier method in Figure 5. The majority of events emerged initially during treatment, within the first week (autonomic NS disorders, 78.1% of the cases; psychiatric disorders, 60.4%; central and peripheral NS disorders, 58.3%; GI system, 56.9%;) or within the second week of treatment (urinary system disorders, 68.8%; CV disorders, 55.4%; vision disorders, 62.5%).

Maximal Severity

The maximal severity of adverse events is grouped by sex and event or body system in Tables 66 and 67, respectively. The majority of events (61.3% of the patients with events), particularly in females (63.8%), but also in males (55.9%) were of mild severity, severe events being reported in 10.2% of the patients. Mildness characterised the severity of events for the vast majority of the affected body system: 81.1% of the patients for the autonomic NS disorders; 79.1% for the GI system disorders; 72.4% for the urinary system disorders; 71.4% for the vision disorders; 67.7% for the central and peripheral NS disorders, 59.0% for the CV disorders; 57.8% for the psychiatric disorders. However, among above commented events, most frequently reported as severe were urinary system disorders, severe in 5 cases (17.2%).

Duration

Summary statistics of the duration of adverse events are described in Table 68. Overall the median duration was of 22 days. Among the most frequent events (8 or more episodes), the median duration was above the overall median figure and up to 39 days for dry mouth, constipation, increased sweating, insomnia, decreased libido, abnormal vision (blurred vision), and tremor; it was below the overall median figure (minimum of 6 days) for headache, urinary retention, tachycardia and paresthesia.

Symptomatic Treatment

As shown in Table 69, 5.3% of the events required symptomatic treatment in 8.6% of the affected patients. Insomnia was the most frequent event leading to symptomatic treatment.

Modification of Study Medication and Patient Outcome

As shown in Table 70, no change in study medication was applied for 89.6% of the events, while the daily dose was reduced in 2.4% of the cases, or the treatment temporarily interrupted in 0.5%. Adverse events were the main reason of treatment withdrawal or contributed to it in 7.2% of the cases. This was most frequently seen for tachycardia (4 cases) and for dry mouth, constipation, libido decreased and urinary hesitancy (2 events each). The individual cases of patients withdrawn due to adverse events are described in Section 8.2.3.2. As shown in Table 71, of the 38 events requiring modification of the study medication, the vast majority (81.6%) disappeared following the modification of the regimen. In fact the patient outcome, grouped by event and action taken on study medication in Table 72, corresponds to full recovery in 78.9% of the cases following modification of the treatment regimen, and in 51.2% of the cases of unchanged study

medication, the event being still present at last assessment in 45.8% of the latter cases or incompletely recovered (recovered with sequelae) in 2.7%.

Relationship Between Adverse Events and Study Medication

The relationship between adverse events and study medication, as judged by the investigators on the basis of Karch and Lasagna modified criteria (Enclosure 9 of Appendix 12.1.1) is described in Table 73. The majority of events (63.6%) were judged possibly related, while 12.8% and 9.9% were judged probably and definitely related, respectively. Among the most frequent events, the maximal frequency of definite/probable relationship was present for dry mouth (36.2%), decreased libido (36.9%), dizziness (33.3%), and urinary retention (37.5%).

8.2.1.2 Double-blind Phase

Absolute and Per Cent Frequency

The absolute and per cent frequency of patients with adverse events and the total number of adverse events newly reported during the run-in open treatment with reboxetine in the two groups of patients subsequently randomised to reboxetine and placebo and those newly reported during the controlled phase of the study are grouped by treatment and sex in Table 74 and by treatment and age classes in Table 75. During the run-in phase, the frequency of adverse events in the females was higher in the patients subsequently randomised to placebo (57.4%) than in those subsequently randomised to reboxetine (50.0%). In contrast, in males the frequency of adverse events was higher in patients subsequently randomised to reboxetine (65.5%) than in those randomised to placebo (58.7%). During the controlled phase, the overall frequency of newly reported adverse event episodes was marginally different in the two treatment groups: 22.8% of the exposed patients in the placebo group (95% C.I. 16.2-30.7%) and 28.0% in the reboxetine group (95% C.I. 20.8-36.1). However in double-blind phase, in males the difference was somewhat more marked (though with largely overlapping C.I.s): 41.4% of the male patients exposed to reboxetine had at least one event, compared with 28.3% of the male patients exposed to placebo. As shown in Table 75, the marginally higher frequency of adverse events under reboxetine is due to the higher frequency of events in patients over 45 years (31.2%, 95% C.I. 20.2-44.1% in the reboxetine group, vs 19.3%, 95% C.I. 10.0-31.9% in the placebo group).

The frequency of patients suffering from adverse events and the frequency of adverse events are grouped by treatment, event and sex in Table 76 and by treatment, body system and sex in Table 77. Most frequently newly reported during the double-blind phase were constipation (8.4 and 4.3% of the patients under reboxetine and placebo, respectively), insomnia (4.9 and 5.0% under reboxetine and placebo), micturition disorder (corresponding to urinary hesitancy, 2.8 and 1.4% under reboxetine and placebo), tachycardia (2.8 and 2.9% under reboxetine and placebo), headache (2.8 and 2.9% under reboxetine and placebo), hypertension (2.8 and 1.4% under reboxetine and placebo), rash (2.1% under reboxetine). The most relevant between-gender difference is related to the frequency of micturition disorders (urinary hesitancy), complained of mainly by male patients (10.3 and

Pharmacia

Document 9550077

2.2% under reboxetine and placebo, respectively). As shown in Table 77, the only between-treatment difference for the most frequently affected body system was related to urinary system disorders, affecting 3.5 and 1.4% of the reboxetine- and placebo-treated patients, and 13.8 and 2.2% of male patients under reboxetine and placebo, respectively.

Occurrence

The time of occurrence of newly reported adverse events in the different time intervals during the run-in reboxetine treatment and double-blind reboxetine or placebo treatment is reported by event in Table 78 and by body system in Table 79. During the double-blind phase, newly reported events mainly emerged initially after randomisation and within the eighth month of therapy, consistently with the selection of the responder and tolerant population with treatment continuation.

Maximal Severity

The maximal severity of newly reported adverse events during the run-in and double-blind phase is grouped by sex and event or body system in Tables 80 and 81, respectively. Similarly to the open phase, during the double-blind phase the majority of patients (72.5% of the patients with events under reboxetine, 81.3% under placebo), particularly females (75.0 and 89.5% in the two groups, respectively), but also males (66.7 and 69.2%, respectively) suffered from events of mild severity. Severe events, however, were reported only under reboxetine in four patients (constipation, tachycardia, perineal pain, chest pain). As for the open phase, mildness characterised the severity of events for the vast majority of the affected body systems in both treatment groups. This was also the case of urinary system disorders, mild in four of the five affected patients under reboxetine (two out of two under placebo).

Duration

Summary statistics of the duration of newly reported adverse events in the run-in and double-blind phase in the two treatment groups are described in Table 82. During the double-blind phase, the overall median duration was 28 days in the reboxetine and 19 days in the placebo group. Among most frequent events, the median duration was higher in the reboxetine than in the placebo group for constipation (91 vs 43 days) and micturition disorders (urinary hesitancy) (118 vs 25 days).

Symptomatic Treatment

As shown in Table 83, during the double-blind phase under reboxetine, 21.4% of the newly emerged events required symptomatic treatment (6.3% under placebo) in 17.5% of the affected patients (6.3% under placebo).

Modification of Study Medication and Patient Outcome

As shown in Table 84, 8 adverse events emerged in the run-in phase caused or contributed to treatment discontinuation after randomisation in the reboxetine group: dry mouth (2 cases), constipation (3 cases), libido decreased (2 cases) and urinary retention (1 case). The

same holds for one case of constipation under placebo. During the double-blind phase, no change in study medication was applied for 87.5% of the events newly emerged in both the reboxetine and placebo groups; reduction of the daily dose was applied in one case of tachycardia in the reboxetine group and treatment was temporarily interrupted in two cases under placebo (headache and hypertension) and one case under reboxetine (perineal pain). Newly emerged adverse events were the main reason for treatment withdrawal or contributed to it in 5 cases under reboxetine (constipation, two events; tachycardia, rash and angina, one event each) and in four cases under placebo (constipation, two events; hypertension and hallucinations, one event each). The individual cases of patients withdrawn due to adverse events during the double-blind treatment are described in Section 8.2.3.2.

As shown in Table 85, the vast majority of the events requiring modification of the study medication disappeared following the change of the regimen. In fact the patient outcome, grouped by event and action taken on study medication in Table 86, for the events occurred during the double-blind phase, corresponds to full recovery in 85.7 and 97.6% of unchanged treatment regimens in the reboxetine and placebo group and in 57.1 and 66.7% of the cases following modification of the reboxetine or placebo treatment, the event still being present at the last assessment in the remaining cases.

Relationship Between Adverse Events and Study Medication

The relationship between adverse events and study medication, as judged by the investigators on the basis of Karch and Lasagna modified criteria (Enclosure 9 of 12.1.1) are described in Table 87. Of the 56 newly emerged events in the reboxetine group, 25.0% were judged probably and definitely related; this was the case for 4.2% of the 48 events newly emerged under placebo. Among most frequent events, the maximal frequency of definite/probable relationship is present for constipation (50.0%, 33.3% under placebo).

Prevalence

The prevalence of patients complaining of adverse events and the prevalence of adverse events in the different time intervals during the run-in reboxetine treatment and double-blind reboxetine or placebo treatment is reported in Table 88. Prevalence of patients with adverse events in the different weeks of treatment of the run-in and double-blind phase is given in Figure 6.

The proportion of patients with adverse events is relatively stable on long-term reboxetine treatment, with a pattern consistent with the selection of the responder and tolerant populations and minimal figures of 25% in the 81 and 79 patients still on treatment at Weeks 50 and 52. On the contrary, it decreases steadily under placebo, up to a minimum of 3% in the 65 patients still on treatment at Week 52.

The prevalence of adverse events in the different time intervals during the run-in reboxetine treatment and double-blind reboxetine or placebo treatment is reported by event in Table 89 and by body system in Table 90. During the double-blind phase, all events have a maximal

prevalence during the first month after randomisation, to decrease steadily thereafter under placebo, while remaining relatively stable under reboxetine. In the 79 patients still on treatment with reboxetine during the twelfth month, maximal prevalence was observed for dry mouth (8.9%, absent under placebo), constipation (8.9%, 1.5% under placebo), micturition disorders (urinary hesitancy, 6.3%, absent under placebo), decreased libido, increased sweating and abnormal vision (blurred vision) (2.5% each, absent under placebo).

8.2.2 ADVERSE EVENT SUMMARY

Of the 358 patients exposed to reboxetine during the open phase of the study, 186 patients (51.9%) reported a total of 374 adverse events (2.0 per patient) (Table 59). The occurrence of adverse events was similar on reboxetine and placebo during the double-blind phase of the study; 40/143 reboxetine recipients (28%) reported 56 adverse events and 32/140 placebo recipients (22.8%) reported 48 adverse events (Table 74). The prevalence of adverse events during the double-blind phase indicates a higher proportion of patients with adverse events in the reboxetine than in the placebo group up to the 1-year assessment (Figure 5).

8.2.2.1 Severity of Adverse Events

The maximum severity of adverse events is presented in Tables 66, 67, 80 and 81 and summarised as follows:

	No. of patients							
	Reboxetine				Placebo			
	Mild	Moderate	Severe	Total	Mild	Moderate	Severe	Total
Open phase	114	53	19	186	-	-	-	
Randomised patients								
Run-in phase	47	24	5	76	52	24	5	81
Double-blind phase	29	7	4	40	26	6	0	32

The majority of adverse events were mild.

8.2.2.2 Age- and Gender-Related Effects

During the open phase of the study, adverse events were reported more frequently in male (62%) than in female patients (48%) (Table 59). More frequent in males were urinary hesitancy (19% vs 1%), urinary retention (7% vs 0.4%) and decreased libido (12% vs 3%) (Table 61). During the double-blind phase of the study also adverse events emerged more

Pharmacia

Document 9550077

frequently in males, particularly under reboxetine (41%, 28% under placebo), than in females (25%, 20% under placebo) (Table 74). Again, urinary hesitancy and retention were more frequent in males (10% and 3%, 2% and 0% under reboxetine and placebo, respectively) than in females (1% hesitancy, under both reboxetine and placebo) (Table 76).

The proportion of patients reporting adverse events during the open phase of the study was minimal for patients aged 46 and over; 57% of patients aged 18-30 years, 59% of patients aged 31-45 years and 44% patients aged 46 years and over reported adverse events (Table 60). This was not confirmed for the events newly emerged during the double-blind phase (Table 75).

8.2.2.3 Frequently Reported Adverse Events

Adverse events which occurred in 5% or more of the patients during the open phase of the study are presented by body system in the following table:

Adverse Events Occurring in 5% of Patients or More - Open Phase (Table 62)

		Reboxetine	
Body system	Adverse event	No. of patients with event	% of patients exposed
Autonomic nervous system disorders	Mouth dry	68	19
	Sweating increased	29	8
Gastrointestinal system disorders	Constipation	60	17
Urinary system disorders	Urinary hesitancy/retention	28	8
Cardiovascular disorders	Tachycardia	22	6
Psychiatric disorders	Insomnia	22	6
	Libido decreased	18	5

Constipation and dry mouth were the most common adverse events during the open phase of the study.

The incidence of adverse events in randomised patients occurring during the double-blind phase of the study is presented overleaf, by body system, for those events that occurred in 2% of patients or more under reboxetine.

Pharmacia

Document 9550077

Adverse Events Occurring in 2% or More of Randomised Patients - Double-blind Phase

Body system	Adverse event	Reboxetine (n=143)		Placebo (n=140)	
		No. of patients with event	% of patients exposed	No. of patients with event	% of patients exposed
Gastrointestinal system disorders	Constipation	12	8	6	4
Psychiatric disorders	Insomnia	7	5	7	5
Urinary system disorders	Urinary hesitancy/retention	5	3	2	1
Cardiovascular disorders	Tachycardia	4	3	4	3
	Hypertension	4	3	2	1
Central and peripheral nervous system disorders	Headache	4	3	4	3
Skin and appendages	Rash	3	2	-	-

Constipation was the most common newly emerged adverse event with 8% of reboxetine recipients and 4% of placebo recipients reporting this event.

8.2.3 SERIOUS ADVERSE EVENTS, DEATHS AND ADVERSE EVENTS LEADING TO WITHDRAWAL

8.2.3.1 Serious Adverse Events and Deaths

Three adverse events (suicide and generalized convulsive episode on open reboxetine, hallucinations on placebo) were reported as serious. Case histories for these patients are provided in Appendix 12.2.1.

8.2.3.2 Adverse Events Leading to Withdrawal

Thirteen patients (3.6%) withdrew from the open phase of the study because of adverse events (Table 3). Eight patients (6 on reboxetine, 4.2%, 2 on placebo, 1.4%) withdrew from the double-blind phase of the study because of adverse events (Table 5). The nature of the adverse events present at withdrawal in these patients is summarised as follows:

Adverse Events Leading To Withdrawal

Study period	Treatment	Patient no.	Adverse event	Relationship to study drug
Open phase	Reboxetine	1-103; 3-5; 3-9; 1-49	Tachycardia	Probable, definite, probable, probable
		10-6; 13-12*	Urinary hesitancy	Possible, unknown
		1-63;10-6	Constipation	Possible, probable
		1-7; 1-63	Libido decreased	Probable, definite
		1-7; 3-6	Dry mouth	Definite
		1-63	Urinary retention	Probable
		10-6	Increased sweating	Possible
		1-49	Vomiting	Definite
		1-103	Dizziness	Probable
			Postural Hypotension	Probable
		1-54	Rash	Probable
		1-57	Diarrhoea	Probable
		1-147	Tremor	Probable
			Agitation	Probable
		3-5	Anxiety	Possible
		3-6	Fatigue	Definite
	Headache	Possible		
3-11	Convulsions	None		
12-30	Suicide	Unknown

8.3 Laboratory Tests

8.3.1 OPEN PHASE OF THE STUDY

8.3.1.1 Summary Statistics of Laboratory Values

Summary statistics of the laboratory values after standardization according to the method proposed by Chuang-Stein (19), are shown by variable and week of treatment in Table 91. Differences vs baseline indicate a significant ($p < 0.01$, Wilcoxon rank signed test) decrease of white blood cells at Week 6 in males (median difference $0.07 \times 10^3/\text{mm}^3$), of gamma GT in males and females at Weeks 2 and 4, and in males at Week 6 (median differences 0.05-0.12 U/l), and of total cholesterol in females at Week 2 and 6 (median differences 0.06-0.08 mg/dl), and a significant increase of phosphate in males and females at Week 2 (median differences 0.11-0.13 mEq/l).

8.3.1.2 Urinalysis

Urinalysis results for each patient are given in Appendix 12.2.2. No abnormalities were detected during the open phase of treatment.

8.3.1.3 Abnormal Laboratory Values

The number and percentage of patients whose values shifted from within, below, or above the normal range to values within, below or above the normal range are given by week in Table 92. A statistically significant shift in the distribution of the frequencies toward lower values was found at Week 2 for neutrophils and at Week 4 for chlorides, while a statistically

significant shift in the distribution of the frequencies toward higher values was found at Week 4 for total proteins and at Week 6 for calcium ($p < 0.01$; Maxwell's test).

8.3.1.4 Abnormal Laboratory Values of Clinical Relevance

The distribution pattern of patients with clinically relevant abnormal values, as defined on the basis of selected criteria (Appendix 12.1.8) are given by variable and week of assessment in Table 93. The frequency of clinically relevant abnormal values was low and similar to baseline, with the possible exception of direct bilirubin which increased more than 100% and up to 191% over the upper limit of the normal range in 2.7% of the patients at Week 4 (1.6% at baseline), but in only 0.7% of the patients at Week 6.

8.3.2 DOUBLE-BLIND PHASE

8.3.2.1 Summary Statistics of Laboratory Values

Summary statistics of laboratory values after standardization according to the method proposed by Chuang-Stein (19), are shown by variable and week of treatment in Table 94.

In the reboksetine group differences vs baseline indicate a significant ($p < 0.01$) increase of red blood cells at Week 42 and 52 in females (median differences $0.06-0.07 \times 10^6/\text{mm}^3$), of monocytes at Week 42 and 52 in females (median differences 0.25%), of beta-globulins at Week 26 and 42 in males (median differences 0.33-0.54 g/dl), of gamma-globulins in females at Week 52 (median difference 0.24 g/dl), of sodium at Week 26, 34 and 42 in females (median differences 0.09-0.10 mEq/l), of phosphates at Week 52 in females (median difference 0.07 mEq/l); and a significant decrease of eosinophils in females at Week 10, 18, 26 and 42 (median differences 0.25%), of gamma-GT in females at Weeks 26, 34, 42 and 52 (median differences 0.10-0.27 U/l), of alkaline phosphatase in females at Weeks 10, 18, 26, 34, 42 (median differences 0.04-0.10 U/l), of alpha I-globulins in females at Weeks 10, 18, 26, 42, 52 (median differences 0.13-0.24 g/dl).

On placebo, differences vs baseline indicate a significant ($p < 0.01$) increase of monocytes at Week 34, 42 and 52 in females and at Week 42 in males (median differences 0.16-0.42%), of total proteins at Week 26 and 34 in males (median differences 0.15-0.20 g/dl), of gamma-globulins in males at Week 18, 26, 34, 42 and 52 (median difference 0.23- 0.50 g/dl), of sodium at Week 26, 42 and 52 in males (median differences 0.18-0.24 mEq/l), of potassium at Week 26, 34 and 42 in males (median differences 0.15-0.20 mEq/l), of phosphates at Week 34 and 42 in females (median difference 0.13-0.25 mEq/l); and a significant decrease of white blood cells in females at Week 10 and 18, and in males at Week 10 (already present at Week 6, on reboksetine), (median differences $0.06-0.08 \times 10^3/\text{mm}^3$), of gamma-GT in females at Weeks 26, 34, 42 and 52 and in males at Weeks 18, 34, 42 and 52 (median differences 0.12-0.22 U/l), of alkaline phosphatase in females and males at Weeks 10, 18, 26, 34, 42 and 52 (median differences 0.13-0.23 U/l), of alpha I-globulins in females at Week 10, 18 and 26 (median difference 0.08-0.18 g/dl), of total cholesterol in females at

Week 34 and 42 (median differences 0.06-0.20 mg/dl), and of triglycerides at Week 26 in males (median difference 0.14 mg/dl).

8.3.2.2 Urinalysis

Urinalysis data for each patient at each visit is presented in Appendix 12.2.2. No abnormalities were detected on randomised treatment.

8.3.2.3 Abnormal Laboratory Values

The number and percentage of patients shifted from values within, below or above the normal range to values within, below or above the latter are given by week in Table 95. In the reboxetine group, a statistically significant shift in the distribution of the frequencies toward lower values was found at Week 26, 42 and 52 for alpha1-globulins (shifted however toward higher values at Week 10), and at Week 10, 18 and 42 for chlorides, while a statistically significant shift in the distribution of the frequencies toward higher values was found at Week 26 and 42 for sodium ($p < 0.01$; Maxwell's test).

In the placebo group, a statistically significant shift in the distribution of the frequencies toward lower values was found at Week 10, 18 and 52 for alpha1-globulins, and at Week 10 and 42 for chlorides, while a statistically significant shift in the distribution of the frequencies toward higher values was found for eosinophils at Week 26 and 42, for monocytes at Week 34, 42 and 52 and for alpha2-globulins at Week 42.

8.3.2.4 Abnormal Laboratory Values of Clinical Relevance

The distribution pattern of patients with clinically relevant abnormal values is given by variable and week of assessment in Table 96. Frequency of clinically relevant abnormal values was similarly low in the two treatment groups over the study period; no significantly increased frequency over baseline was present for any of the variables measured in both reboxetine and placebo recipients.

8.4 Vital Signs

8.4.1 BLOOD PRESSURE AND HEART RATE

8.4.1.1 Open Phase

Summary statistics of blood pressure and heart rate values and changes vs baseline at each visit during the open phase of the study are presented in Table 97a-f and 98, respectively. There were no important trends apparent in mean and median vital signs values and changes during the open phase of the study.

The frequency of patients at each visit of the open phase who showed a modification of 20% or more vs baseline or such a modification accompanied by absolute critical values

(≥ 160 or ≤ 100 mmHg for systolic blood pressure; ≥ 100 or ≤ 70 mmHg for diastolic blood pressure; ≥ 100 or ≤ 50 beats/min for heart rate) are given in Tables 99 and 100, respectively. Similar proportions of patients (maximum 6%) showed an increase and a decrease of possible clinical relevance for the systolic blood pressure in lying and standing position and for the diastolic blood pressure in standing position. For the lying diastolic blood pressure, the proportion of patients with an increase of possible clinical relevance was slightly higher (6-10%) than the proportion of patients with a decrease (3-4%). For the heart rate, the proportion of patients with at least 20% increased values (13-21% and 18-21% in lying and standing position, respectively) was always higher than the proportion of patients with at least 20% decreased values (5-6% and 3-6% in lying and standing positions, respectively).

Similar proportions of patients (maximum 3%) showed an increase and a decrease of possible clinical relevance associated to critical values for the systolic blood pressure in lying position. For the lying diastolic blood pressure and for the standing systolic and diastolic blood pressure, the proportion of patients showing a decrease was always higher than those showing the opposite, the maximal difference being observed in standing position (0.3-0.8% vs 1.8-3.7% for the systolic; 0.3-2.4 % vs 4-5.7 % for the diastolic). Almost no patient showed a clinically relevant decrease of heart rate to values of 50 beats/min or lower, while 5-8% in lying and 9-13% in standing had an increase of at least a 20% associated with values of 100 beats/min or higher.

The number and percentage of patients with orthostatic hypotension (a decrease of > 20 mmHg in the standing systolic blood pressure as compared to the lying pressure) at each visit are presented in Table 101. The event had a low frequency at all visits, affecting a maximum of 2% of the patients at Week 3, with no major changes in frequency vs baseline.

8.4.1.2 Double-blind Phase

Summary statistics of blood pressure and heart rate values and changes vs baseline at each visit during the double-blind phase of the study are presented in Table 102a-f and 103, respectively. There were no important trends apparent in mean and median blood pressure values and changes during the double-blind phase as compared to the run-in reboxetine treatment, while the heart rate mean and median values and changes indicate maintenance on reboxetine of the small increase observed in the run-in phase, while a slight decrease was apparent on placebo.

The frequency of patients at each visit of the double-blind phase showing a modification of 20% or more vs baseline or such a modification accompanied by absolute critical values (≥ 160 or ≤ 100 mmHg for systolic blood pressure; ≥ 100 or ≤ 70 mmHg for diastolic blood pressure; ≥ 100 or ≤ 50 beats/min for heart rate) are given in Tables 104 and 105, respectively.

During the run-in phase, the proportion of patients with an increase of possible clinical relevance of the lying diastolic blood pressure was slightly higher than the proportion of

patients with a decrease in the group subsequently randomised to reboxetine. During the double-blind phase, the proportions of patients showing an increase and a decrease of possible clinical relevance for the systolic and diastolic blood pressure in lying and standing position were similar to the one apparent in the run-in phase in both reboxetine and placebo groups. As for the lying and standing heart rate, the higher proportion of patients with at least 20% increased values apparent in the run-in phase continued to be observed during the double-blind phase in the reboxetine-treated patients, but not in the placebo-treated ones.

The proportions of patients showing a decrease of possible clinical relevance of blood pressure associated with critical values tended to be slightly higher than those showing the opposite for all blood pressure measurements in the run-in and double-blind phase on both reboxetine and placebo. The proportions of patients with an increase of heart rate of at least 20% associated with critical values were always more prevalent than the opposite during the run-in and double-blind phase in both treatment groups and particularly on standing. However, during the double-blind phase a progressive decrease of the proportion of patients with this event was observed on placebo (present in 0 to 7% of the patients at the different visits), but not on reboxetine (present in 8 to 18%).

The number and percentage of patients with orthostatic hypotension at each visit are presented in Table 106. As reported for the open phase, the event had a low frequency at all visits, affecting a maximum of 3.6% of the patients on reboxetine and of 2.1% of the patients on placebo.

8.4.2 BODY WEIGHT

Summary statistics of the body weight values (Kg) during the open and double-blind phase of the study are given in Tables 107 and 108, respectively. No trends toward modification and no difference between the reboxetine and placebo groups were apparent.

8.4.3 BODY TEMPERATURE

Summary statistics of the body temperature values (°C) during the open and double-blind phase of the study are given in Tables 109 and 110, respectively. No trends toward modification and no difference between the two treatment groups were apparent.

8.5 Ophthalmological Examination

The results of the intraocular pressure measurement and of the global assessment of the detected abnormalities at baseline and at the last control visit of the double-blind treatment in the randomised patients are listed in Appendix 12.2.2. No modifications of note were apparent in either treatment group.

8.6 Electrocardiogram

8.6.1 OPEN PHASE

As shown in Table 111, among the 355 patients with ECG recorded at baseline and at least once during the open phase, 56 (15.8%) showed at least one ECG abnormality at entry into the study. This percentage frequency remained stable at the assessments made every two weeks up to Week 6, when 14.1% of the 319 evaluated cases had at least one abnormality. As shown in Table 112, during the fortnightly assessments of the open phase, frequency of normalisation of ECG recordings in patients with at least one abnormality at entry was always consistently higher (52.8, 43.4 and 54.9%) than frequency of at least one newly emerged abnormality in patients with normal tracing at baseline (7.4, 7.5 and 8.2%). At the last assessment of the open phase, of the 56 patients with at least one abnormality at baseline, 53.6% were reportedly normal, while among the 299 patients with normal tracings at baseline, 9.0% showed at least one abnormality (Table 113).

The frequency of individual abnormalities at admission and every two weeks during the study is shown in Table 114. In baseline conditions, individual abnormalities are present in a maximum of 5.1% of the 355 evaluated cases (sinus tachycardia). During treatment the frequencies of all observed abnormalities were not modified to any significant extent. As shown in Table 115, at the last assessment of the open phase, for all abnormalities the proportion of newly observed cases among normal baseline cases is lower than the proportion of normalised cases among abnormal baseline cases. Newly emerged abnormalities never reported at baseline include left bundle branch block and repolarisation disturbances, recorded in one and two cases, respectively.

The frequencies of patients with at least one abnormality by abnormality group are shown in Table 116. At baseline, from 2.8% (other disorders) to 6.2% (rhythm disorders) of the evaluated patients showed at least one abnormality of the indicated groups. The percentage frequencies were not modified to any significant extent up to Week 6. As shown in Table 117, at the last assessment of the open phase, for all abnormality groups, the proportion of newly emerged cases was far lower than the proportion of normalised cases.

8.6.2 DOUBLE-BLIND PHASE

As shown in Table 118, among the 135 patients with ECG recorded at baseline and at least once during the double-blind phase in each treatment group, 14.2 and 16.3% in the reboxetine and placebo group, respectively, had at least one ECG abnormality recorded at the end of the reboxetine open treatment. At the two-monthly assessments up to Week 52, the proportion of abnormal ECG recordings was similar in the two treatment groups, in the range of 13.4 to 6.4% in the reboxetine- and 15.4 to 7.0% in the placebo-treated patients.

As shown in Table 119, during the two-monthly assessments of the double-blind phase, the frequency of normalisation of ECG recordings in patients with at least one abnormality at entry was always consistently higher than the frequency of at least one newly emerged abnormality in patients with normal tracing at baseline in both treatment groups. At the last assessment of the double-blind phase (Table 120), of the 22 patients with at least one abnormality at baseline in either treatment group, 72.7 and 59.1% were reportedly normal in the reboxetine and placebo groups, respectively, while among the 113 patients with normal tracings at baseline in either treatment group, 6.2 and 4.4% of the reboxetine and placebo recipients showed at least one abnormality.

The frequency of individual abnormalities at admission and during the open reboxetine and double-blind treatment phases in randomised patients is shown by treatment group in Table 121. At the end of the open reboxetine treatment individual abnormalities are present in a maximum of 4.5% (non-specific ST-T wave changes and sinus tachycardia) of the 134 evaluated cases of the reboxetine and in 5.9% (sinus tachycardia) of the 135 evaluated cases of the placebo group. During the double-blind treatment, the percentage frequencies of all observed abnormalities were not modified to any significant extent in either treatment group. As shown in Table 122, at the last assessment of the double-blind phase, for all abnormalities and both treatment groups, the proportion of newly observed cases among normal baseline cases is lower than the proportion of normalised cases among abnormal baseline cases. Abnormalities never reported at baseline newly emerged in rare cases and with similar frequency in the reboxetine and placebo groups.

The frequencies of randomised patients with at least one abnormality by abnormality group during the open reboxetine and double-blind treatment are shown in Table 123. At the end of the open reboxetine treatment, from 2.2% (other disorders) to 6.7% (ischemic signs and rhythm disorders) of the evaluated patients in the reboxetine group and from 1.5 (other disorders) to 8.1 (rhythm disorders) in the placebo group showed at least one abnormality of the indicated groups. During the double-blind phase, the proportion of patients with at least one of each group of abnormalities was not modified to any significant extent in either treatment group. As shown in Table 124, at the last assessment of the double-blind phase, for all groups of abnormalities, the proportion of newly emerged cases was similar in the two treatment groups, and in both groups far lower than the proportion of normalised cases.

8.7 Safety Conclusions

All the patients who received study treatment were included in the safety analysis, i.e. 358 patients in the open phase and 283 patients (143 reboxetine, 140 placebo) in the double-blind phase of the study.

During the open phase of the study, 52% of the patients reported adverse events and 3.6% discontinued reboxetine medication due to adverse events. Most frequently reported were dry mouth (19% of the patients), constipation (17%), urinary hesitancy/retention and increased sweating (8%), tachycardia and insomnia (6%), and decreased libido (5%). The

occurrence of newly reported adverse events was similar on reboxetine and placebo during the double-blind phase of the study; 40/143 reboxetine recipients reported 56 adverse events compared with 32/140 placebo recipients who reported 48 adverse events; however, the prevalence of adverse events was higher in the reboxetine than in the placebo group and discontinuation due to adverse event was more frequent on reboxetine (4.2%) than on placebo (1.4%). Most frequently newly reported was constipation (8% on reboxetine, 4% on placebo). The majority of adverse events were mild. Adverse events were reported more frequently by men than women, particularly on reboxetine. This was particularly the case for urinary hesitancy, urinary retention and decreased libido. There were three serious adverse events during the study (suicide and generalized convulsive episode on open reboxetine, hallucinations on placebo). The one death was the result of suicide.

There was no indication of modifications in laboratory tests that were of clinical significance.

Vital signs were not modified to any significant extent, with the exception of heart rate, which was significantly increased (20% or more) under reboxetine to values of 100 beats/min. or higher in approximately 10 to 15% of the patients, also on long-term treatment and particularly on standing.

No indication of effect on cardiac function emerged from ECG recordings. The ophthalmologic examination did not provide indications of treatment related changes.

9. DISCUSSION

This was a multicentre, double-blind study to investigate the efficacy and tolerability of reboxetine compared with placebo in patients with a DSM-III-R diagnosis of Major Depressive Disorder and an HAMD total score of at least 18. After an initial period during which patients received reboxetine 4 mg bid for six weeks, responders (50% or greater decrease of the HAMD total score) were randomised to receive maintenance therapy with reboxetine 4 mg bid or placebo for up to one year. The study end-points were frequency and time to relapse and frequency of remission at last assessment of the double-blind treatment phase and these were to be compared between treatment groups. Three hundred and fifty-eight patients entered the open phase of the study, 286 entered the randomised phase of the study, 143 received reboxetine and 140 placebo; among whom 133 and 132 were responders at Week 6 and were considered evaluable for efficacy; 79 reboxetine and 65 placebo recipients completed the 1-year treatment period. Of the 36 patients withdrawn from the open phase, one patient committed suicide, 13 dropped out due to adverse events, and 10 for lack of efficacy. During the double-blind phase of the study, 6 reboxetine recipients and 2 placebo recipients withdrew due to adverse events. Thirty-six and 17 discontinued placebo and reboxetine medication, respectively, according to protocol provisions, due to deterioration of the clinical picture, the time pattern of discontinuations not related to deterioration being similar in the two treatment groups.

Efficacy. At the end of open reboxetine, 76% of patients were responders and 50% of patients were in remission (HAMD total score 10 or less). At the last assessment of the open reboxetine treatment, the HAMD total score was reduced from 29.6 at baseline to 12.9, the MADRS total score from 18.4 to 7.8, while the percentage of patients whose condition was “very much improved” and “much improved” according to CGI scores was 45.8 and 31.3, respectively. These results, though obtained in uncontrolled conditions, strongly support the antidepressant efficacy of reboxetine in the therapy of acute depressive episodes.

Among the 133 responder patients randomised to reboxetine, 21.8% relapsed during the long-term treatment, while 56.1% of the 132 responder patients randomised to placebo relapsed, the between-treatment difference being highly significant. The time pattern of the relapse rate analysed according to the Kaplan-Meier method indicates a significantly increased risk of relapse on placebo compared with reboxetine. The proportion of patients in remission at the last assessment of the double-blind treatment phase was significantly higher on reboxetine (78.2%) than on placebo (44.7%). The analysis of the study end-points proves the efficacy of reboxetine in the maintenance therapy of Major Depressive Disorders, the between-treatment difference being statistically and clinically highly significant.

These results are confirmed by the analysis of the secondary efficacy variables. In the 133 responder patients randomised to reboxetine, the mean HAMD score was reduced from 29.2 at baseline to 8.8 at Week 6 and to 5.9 at Week 52 in the 76 assessed patients still on maintenance reboxetine. In the 132 responder patients randomised to placebo, HAMD scores fell from 30.1 to 9.1 at Week 6 but increased to 11.1 at Week 52 in the 62 assessed patients still on treatment. Similarly, the mean total MADRS scores fell from 5.3 at Week 6 to 3.1 at Week 52 in the 76 assessed patients still on maintenance reboxetine, compared with a rise from 5.3 to 7.0 in the 62 patients on placebo. The percentage of patients whose CGI score was “very much improved” increased from 62.4% at Week 6 to 94.7% at Week 52 on reboxetine in contrast to a marginal increase from 57.6% to 64.5% at Week 52 on placebo.

The additional analysis of the frequency of maintenance of the response during the initial six months and subsequent six months of treatment indicates that the advantage over placebo in the maintenance of the response is present also in the second half of the one year treatment period (88.0 vs 59.2% of the reboxetine- and placebo-treated patients, respectively). As reported for imipramine [25], sertraline [26] and paroxetine [27], the observed findings can be interpreted as indicative of a preventive effect, not only of relapse of the index episode, but also of the recurrence of new episodes.

The additional analysis on the subset of patients in remission at the end of the open phase confirmed literature data [28] on the increased risk of relapse in patients with residual

depressive symptoms, as well as the advantage of reboxetine over placebo in the population in remission at randomisation.

Safety. Reboxetine had no effect of clinical significance on either laboratory tests, ECG, ophthalmoscopic examination or vital signs during either the acute or the long-term treatment phase, with the exception of the heart rate, which was significantly increased (20% or more) under reboxetine to values of 100 beats/min or higher in approximately 10 to 15% of the patients, also on long-term treatment and particularly on standing.

During the open phase of the study, 52% of the patients reported adverse events and 3.6% discontinued reboxetine medication due to adverse events. Most frequently reported were dry mouth (19% of the patients), constipation (17%), urinary hesitancy/retention and increased sweating (8%), tachycardia and insomnia (6%), libido decreased (5%).

The occurrence of newly reported adverse events was similar on reboxetine and placebo during the double-blind phase of the study: 40/143 reboxetine recipients reported 56 adverse events compared with 32/140 placebo recipients who reported 48 adverse events. Prevalence of adverse events was higher in the reboxetine than in the placebo group. Discontinuation due to adverse event was infrequent, but more frequent on reboxetine (4.2%) than on placebo (1.4%). The most frequently newly reported event was constipation (8% on reboxetine, 4% on placebo).

The majority of adverse events were mild. Adverse events were reported more frequently by men than women, particularly on reboxetine. This was particularly the case for urinary hesitancy, urinary retention and decreased libido. Three serious adverse events were reported during the study (suicide and generalized convulsive episode on open reboxetine, hallucinations on placebo). The one death was the result of suicide.

10. CONCLUSION

The efficacy of reboxetine maintenance therapy in responders, as measured by HAMD, MADRS and CGI scales, was markedly superior to that of placebo in patients with major depression, when administered for up to one year. The tolerability of reboxetine administered on a long-term basis was highly acceptable, as shown by the safety profile which was marginally superior to that of placebo for the incidence of adverse events and for clinically significant tachycardia and similar to placebo for modifications of other vital signs, haematology and blood chemistry tests, ophthalmologic and ECG examinations.

**AMENDMENT 1 to the
REBOXETINE PROTOCOL 20124/013**

The paragraph 9.1 will be as follow:

9.1. Pre-treatment period

Patients will be checked for eligibility according to the inclusion and exclusion criteria. A washout period of 4-7 days (14 days in case of MAOI administration, and 3-4 weeks in case of previous fluoxetine treatment) will then be undertaken, during which only chloral hydrate (0.5 - 1.0 g) as sleep inducer on p.r.n. basis will be allowed. Informed consent will be obtained from each patient and/or next of kin.

Eligible patients will be then randomized to one of the treatment groups and will undergo baseline assessments.

Information on patients screened for the study and found not to be eligible will be collected in the appropriate form (screening form, enclosure 3).

1.0 PROTOCOL SUMMARY

The study, aimed at the evaluation of the efficacy of reboxetine in comparison with placebo in the maintenance therapy of acute episodes of Major Depressive Disorders and the tolerability of the compound upon long term administration, will be carried out on a multicenter, multinational basis, according to a double-blind parallel group design, in 300 patients. After an initial washout period of 1-2 weeks, patients will receive reboxetine 4 mg b.i.d. for 6 weeks. Responders (50% decrease of the total score of the Hamilton Depression Rating Scale, HAMD-Encl.4) will be randomized to treatment with either reboxetine or placebo, administered according to a fixed dose regimen, up to relapse (HAMD total score increased of at least 50% and greater than 18) or up to a maximum treatment period of one year. Efficacy (HAMD, Montgomery-Asberg Depression Rating Scale-Encl.6, Zung self-rating Depression scale-Encl.7) and tolerability (newly observed signs and symptoms, lab tests and ECG) will be assessed at weekly, or weekly-monthly intervals. A long-term follow-up could then be undertaken.

2.0 INTRODUCTION

Reboxetine (FCE 20124 or RS, RS 2-[α -(2-ethoxy-phenoxy) benzyl] morpholine methanesulphonate is a chemically new compound highly potent in pharmacological and biochemical tests predictive of antidepressant effectiveness: reserpine antagonism, norepinephrine reuptake inhibition, REM sleep latency increase. In addition reboxetine has been found to be able to prevent clonidine effects in rodents after single oral administration, in contrast with what observed following tricyclic monoamine uptake inhibitors, which were found to be active only upon repeated doses: these results indicate that the compound is able to decrease the sensitivity of α_2 noradrenergic receptors, one of the biochemical correlates of chronic antidepressant treatment, after single oral dose: therefore it may be expected to exert antidepressant effectiveness of faster onset with respect to available antidepressants in patients (1).

In phase I studies healthy volunteers (2, 3) were orally administered single doses of 0.5 - 5 mg of compound. After 5mg orthostatic hypotension, accompanied by tachycardia and by subjective symptomatology consistent with the disturbed circulatory regulation was observed.

In these studies single doses of 1 & 3 mg of the compound showed dose-dependent CNS effects with EEG modifications (decreased power of theta and fast-beta waves in the fronto-central derivative), performance improvement

FARMUTAJA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

(peg-board test) and growth hormone increase, the latter reportedly sensitive to hypothalamic noradrenergic stimulation by norepinephrine reuptake inhibitors.

The comparison with the positive control, imipramine 75 mg, associated to similar EEG modifications in the fronto-central derivative, to modifications indicative of sedative activity in the occipito-temporal derivative and to deterioration of the Pauli performance test, in the absence of growth hormone modifications, indicate that reboxetine does not possess the marked sedative activity of imipramine, but rather psychostimulating properties. After all treatment standing heart rate increase and salivation decrease was apparent. No other modifications of tolerability parameters were observed.

The pharmacokinetics of the compound was evaluated in the above mentioned studies as well as after administration of 2 mg ¹⁴C-FCE 20124 to 3 healthy volunteers (4). Most of the radioactivity circulating in plasma (73% in terms of AUC) was accounted for by unchanged reboxetine; the average peak levels were observed at 2 h, with remarkably stable levels 1-6 hours after administration; its plasma half-life was estimated as 13.2 h, slightly lower than that of total radioactivity.

In addition the autonomic effects of the compound have been evaluated in a study carried out in 16 healthy volunteers according to a double-blind, latin square experimental design. Single doses of reboxetine 1, 2 & 4 mg, desipramine 25, 50 and 100 mg and placebo were administered at weekly intervals. Both reboxetine and desipramine were found to be similarly active in reducing salivation and antagonizing carbachol-evoked sweating, activities consistent with anticholinergic properties, and in increasing heart rate (consistent with muscarinic receptor blockade and/or noradrenergic stimulation); reboxetine, but not desipramine, was found to increase resting pupil diameter (consistent with muscarinic receptor blockade and/or α -stimulation) and to antagonize light evoked-miosis (consistent with anticholinergic activity).

Neither reboxetine nor desipramine were found to modify phenylephrine evoked sweating (no evidence of α -adrenoceptor blockade); following reboxetine a reduction of phenylephrine-evoked mydriasis was apparent, possibly due to a "ceiling effect" (due to the mydriatic effect of reboxetine) rather than α -adrenoceptor blockade. No evidence of noradrenaline-uptake blockade could be observed, since noradrenaline failed to evoke measurable pupillary response.

9550077

On the basis of the results of the phase I studies, a 6-center early phase II study was carried out aimed at assessing tolerability and activity of progressively increased doses of reboxetine, administered over a 4-week period to hospitalized patients suffering from Major Depressive Disorders.

Ninety-eight patients were admitted to the study to be treated with maximum reboxetine daily doses of 4 mg (29 pts), 6 mg (27 pts), 8 mg (18 pts), 10 mg (12 pts) and 12 mg (12 pts). Treatment was discontinued in 4 patients in the 4 mg group due to deterioration of the clinical picture (with a manic syndrome in one case); in 2 patients of the 6 mg group due to the development of a manic episode; in one patient of the 6 mg group due to a convulsive episode, under associated treatment with levomepromazine. Dosage decrease was almost only present in the 12 mg group where in 5/12 cases, due to hypotension and tachycardia, the daily dose was decreased to 10 mg up to completion of the treatment period.

The rating scales applied showed dose related improvement of the clinical picture both as average changes vs basal conditions as well as frequencies of relevant modifications (defined as 50% decrease of HAMD) up to the 10 mg/day dose, whereas slight deterioration, concomitant to the intolerance signs/symptoms, was observed in the highest dose group.

The compound was well tolerated when administered up to the dose of 10 mg/day, as shown by newly observed signs and symptoms, mainly of mild to moderate severity and transient, and by vital signs and lab tests assessments, ECG included.

A double blind parallel group study was subsequently carried out in 10 centers (Hungary, Italy, France and Latin America) in 258 patients hospitalized due to a Major Depressive Episode. The experimental treatment had to be administered for 4 weeks, with maximum doses of 8 mg reboxetine(RBX) or 200 mg desipramine(DMI). The experimental treatment was discontinued in 26 patients (10%): in 18 cases (5, 6 e 7 of the RBX, DMI and P group respectively) for inefficacy; in 3 cases for adverse events (2 of the RBX group due to deterioration of the ventricular extrasystoles present before study start and hypertensive episodes respectively and 1 of the placebo group due to a cutaneous rash); in 5 cases (2, 1 and 2 in the RBX, DMI and P group respectively) for reasons unrelated to the experimental treatment.

FARMITALIA CARLO ERBA
ERRAMONT GROUP
CNS Line - Medical Research

9550077

Of the 80, 82 and 81 cases evaluable for efficacy in the RBX, DMI and P group (after exclusion of protocol violations, mainly related to associated treatments) 63%, 46% and 36% respectively showed a decrease >50% of the HAMD total score at the end of treatment; in 31%, 22% and 21% of these patients respectively the decrease was present within the 14th day at treatment. As to within-center results, the highest frequency of response was observed in the RBX group in all but 3 of the participating centers. After 2 and 4 weeks of treatment an average decrease of 23% and 34% of the HAMD was present in the P group; the corresponding figures were 34% and 49% in the DMI group and 39% e 57% in the RBX group.

As to signs/symptoms, more frequent in the RBX group were headache, complained of by 33% of the patients (20% and 21% in the DMI e P group respectively), and urinary hesitancy/retention, present in 12% vs 4% vs 1% of the cases, RBX vs DMI vs P. More frequent in the DMI group were dry mouth (45% vs 26% vs 21%, DMI vs RBX vs P), sweating (28% vs 18% vs 22%), blurred vision (17% vs 4% in both RBX and P groups). Cardiovascular signs/symptoms were relatively rare, and appeared with slightly higher frequency in the DMI group: hypotension 13%, vs 6% in the RBX and 8% in the P group and tachycardia 19% vs 12% and 8% in the RBX and P group respectively.

3.0 RATIONALE

Phase II results obtained in controlled conditions in patients suffering from Major Depressive Disorders indicate that reboxetine is an effective antidepressant agent, with a favourable therapeutic index with respect to desipramine. The efficacy of the compound in the continuation therapy of Major Depressive Episodes needs now to be tested in controlled conditions vs placebo. In addition the tolerability of the compound upon long-term administration has to be evaluated.

4.0 OBJECTIVES

To assess activity and tolerability of reboxetine in comparison with placebo in the continuation therapy following response in patients suffering from Major Depressive Disorders.

FARMITALIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

5.0 DESIGN

5.1 Description

This phase III study will be carried out according to a double blind parallel group design, controlled vs placebo, with random allocation of patients to one of the two treatments. The study will be organized on a multicentre, multinational basis.

5.2 Number of Subjects Proposed

Each center will recruit enough patients to collect a sample of 30 patients, fulfilling the criteria for entering the double blind phase within a period of one year, for a total of 300 patients overall.

5.3 Logistics

The following 10 centers will participate in the study:

1° BRAZIL - Institute of Psychiatry, Federal University
Rio de Janeiro
Principal Investigator: Prof. M. Versiani
Associate Investigator: Dr. A.E. Nardi

2° DDR - Wilhelm Pieck Universität Rostock
Rostock
Principal Investigator: Prof. K. Ernst

3° FRANCE - Université Aix-Marseille Laboratoire de
Traitement des Connaissances - Faculté de Médecine
Marseille Cedex
Principal Investigator: Prof. M. Ohayon

4° FRANCE - Laboratoire de Pharmacologie Clinique
Centre Hospitalier Ponchaillou
Rennes
Principal Investigator: Prof. H. Allain
Associate Investigators: Dr. J.M. Gandon, Dr. J.P. Martinet

5° PANAMA - National Psychiatric Hospital.
Panama
Principal Investigator: Dr. L. Vergara

6° PANAMA - National Psychiatric Hospital.
Panama
Principal Investigator: Dr. R. Batista

7° POLAND - Klinika Psychiatryczna

FARMUTALIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

Szczecin
Principal Investigator: Dr. M. Jarema

8° HUNGARY - Psychiatric Dept. "Janos" General Hospital
Budapest
Principal Investigator: Dr. A. Lipcsey
Associate Investigator: Dr. E. Nagy

9° HUNGARY - National Institute for Nervous and Mental
Diseases
Budapest
Principal Investigator: Dr. P. Gaszner
Associate Investigator: Dr. A. Tar

10° USSR - Dept. of Psychiatric, University
Tartu Estonia
Principal Investigator: Prof. L. Mehilane
Associate Investigator: Dr. P. Laame

6.0 STUDY POPULATION

6.1 Source of Subjects

Adult patients selected from the population attending out-patient clinics or newly admitted (within 2 weeks) to the Psychiatric Dpt of the participating centers will be studied.

6.2 Inclusion Criteria

- Patients affected by acute recurrences of Major Depressive Disorders, not accompanied by psychotic features (DSM IIIr) with the CODE DD variables: "Acute onset" or "Subacute onset" present and "Prolonged duration" absent.
- Patients of either sex, of any race, aged 18 to 65 years.
- A total score of 18 or above in the 21-HAMD.
- Patient's consent: informed consent will be obtained from the patient and/or next of kin (proposed consent form: Enclosure 1).

6.3 Exclusion Criteria

- First episodes of Major Depressive Disorders
- History of Major Depressive Disorders associated to

20124/013

Date: 28/2/90

Page: 6 of 22

Endocrine Disorders: hypo and hyper-thyroidism tested by rT3, followed by T3 and T4 in case of negative finding at admission; adrenal insufficiency, etc.

- Pregnancy (tested by pregnancy test at the end of the wash-out period).
- Refusal of contraceptive use during the study period.
- Past history of drug hypersensitivity.
- Participation in a clinical study with an investigational compound in the 4 weeks preceding the study.
- Evidence of Substance Use Disorder within past 6 months or currently.
- Chronic respiratory insufficiency
- History or presence of gastrointestinal, liver, or kidney disease, or other conditions known to interfere with the absorption, distribution, metabolism and excretion of drugs.
- History of seizures or serious brain injury; current evidence of clinically important hematopoietic or cardiovascular diseases. Current evidence of urinary retention or glaucoma.
- Symptoms of any other important clinical illness in the 4 weeks preceding the study.
- Clinically relevant abnormal findings in the physical examination, laboratory tests and ECG at admission.
- ECT in the previous 6 months.

6.4 Identification of Subjects

Patients will be identified by their initials and by the number in the trial.

7.0 RANDOMIZATION PROCEDURES

A randomization list balanced within center will be prepared for patient allocation to one of the 2 possible treatments (reboxetine or placebo). On this basis the experimental treatments will be prepared and labelled with the corresponding patient number.

FARMITALIA CARLO ERBA
ERRAMONT GROUP
CNS Line - Medical Research

9550077

Patient allocation to treatment will be done at the end of the 6 weeks open treatment of the acute episode (see Study Conduct) by the principal Investigator on the basis of the patient's temporal entry into the study.

8.0 EXPERIMENTAL TREATMENTS

8.1 Test Preparation

Indistinguishable scored tablets containing either reboxetine 4 mg plus excipients (batch no SF1030) or excipients only (placebo, batch no SF1032) will be used.

8.2 Labelling

The experimental treatment will be labelled by using the labels in enclosure 2. Double labels will be used (see point 8.5).

8.3 Packaging

For the open initial treatment of the acute episode (see Study Conduct) 6 glass amber bottles labelled with the patient number and the indication week 1 to 6 will be prepared for each patient. Each bottle will contain the medication necessary for each of the first 6 weeks of treatment with reboxetine, i.e. 16 tablets (1 tab 4 mg b.i.d. plus 2 additional for possible losses).

In addition for the double blind continuation therapy following response (see Study Conduct) 30 glass amber bottles labelled with the patient number and the indication week 7-8, week 9-10, week 11-12, etc, up to week 51-52 will be prepared for each patient. Each bottle will contain the medication necessary for each of the two-week treatment periods between visits up to the maximum of one year , i.e. 32 tablets of either reboxetine 4 mg or placebo (1 tab b.i.d. plus 4 additional for possible losses).

8.4 Drug Supplies Storage

Drug supplies will be stored at room temperature. All drug supplies will be handled under the direct responsibility of the Investigator and held by the Hospital Pharmacy. The study Monitor will check drug storage conditions during site visits.

20124/013

Date: 28/2/90

Page: 8 of 22

FARMITALIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

The Investigator will be also responsible for drug accountability and will keep a record of the test compounds received from the Sponsor as well as of the dispensed drug.

8.5 Dispensing, Use and Disposal of the Test Preparation during and at the End of the Study

Medication will be dispensed to the patient on the occasion of each visit; the Investigator will detach the upper label from each of the weekly cartons he is dispensing to the patient and will attach them in the appropriate space in the Case Record Form. On the same occasion cartons of the possible previous supply will be returned by the patient.

Used cartons will be returned to the study Monitor during site visits.

All unused medication has to be returned to Farmitalia Carlo Erba at the end of the study.

9.0 STUDY CONDUCT

9.1 Pre-Treatment Period

Patients will be checked for eligibility according to the inclusion and exclusion criteria. A washout period of 7 days (14 days in case of MAOI administration) will then be undertaken, during which only chloral hydrate as sleep inducer on p.r.n. basis will be allowed. Informed consent will be obtained from each patient.

Eligible patients will then undergo baseline assessments.

Information on patients screened for the study, including those not eligible, will be collected in the appropriate form (screening form, enclosure 3).

9.2 Treatment Period

9.2.1 Dose/Route of Administration/Treatment Schedule

Patients will receive 1 tablet of reboxetine 4 mg b.i.d. from day 1 to day 42, i.e. for 6 weeks. At the end of this open treatment phase patients showing response (see Efficacy Definitions) will be randomized to treatment with either reboxetine or placebo (1 tab b.i.d.) for a maximum period of one year or up to relapse (see Efficacy Definitions).

20124/013

Date: 28/2/90

Page: 9 of 22

The daily dose can be reduced by half tablet (2 mg for reboxetine) in case of emergence of non tolerable signs or symptoms.

The treatments will be administered in the morning (10 a.m.) and in the evening (6 p.m.). Treatment intake will take place at least 2 hours before or after meals.

9.2.2 Duration of Treatment

Following the initial open treatment with reboxetine for 6 weeks, the experimental treatment with either reboxetine or placebo will be administered for a maximum period of one year.

9.2.3 Indications for Early Termination of Test Therapy

Termination of test therapy prior to completion of the treatment period may be considered under the following circumstances:

- Patient's request.
- Unacceptable toxicity: this is defined as the occurrence of serious and unexpected (see Adverse Events) adverse events or the persistence of non tolerable signs or symptoms which are not alleviated by reducing the dose to the lower dosage level.
- Inefficacy during the open initial treatment phase: this will apply to patients who after completion of at least 2 weeks of treatment will show worsening of the global clinical picture (CGI - Global Improvement, see assessments).

In case of treatment discontinuation the final complete battery of assessments will be carried out wherever possible.

9.2.4 Dropouts/Replacement of Subjects

Patients who drop out of the study for any reason during the open treatment phase will be substituted in order to have in each Center a sample of 30 patients entering the double blind treatment phase.

Patients who drop out of the study for any reason during the double blind treatment phase will not be substituted.

For those patients who have been selected for the study who drop out at any time, even if it is before entrance to the treatment period, documentation will be provided.

9.2.5 Concomitant Therapy

No concomitant medications are allowed during the study. In case of events arising during the course of the study non psychotropic medications which are considered necessary for the patient's welfare may be administered and will not be considered protocol violations. The drugs, dosage and frequency of administration will be recorded on CRF. Chloral hydrate as a sleep inducer on p.r.n. basis at bed-time is allowed.

9.2.6 Indications for Opening the Code

The Investigator will be given individual sealed envelopes containing the information on patient's treatment. These latter may be opened only in case of emergency necessitating treatment identification; the Investigator will immediately (within 24 hours) inform the study Monitor at FICE Subsidiaries and will report full description of reasons for opening the code in the CRF (Adverse Event Form).

The sealed individual codes will be returned to Farmitalia Carlo Erba at the end of the study.

9.3 Follow-up

Patients willing to continue receiving the experimental treatment after completion of the one year treatment period will be maintained under the same medication in blind conditions until completion of the last patient of the center.

A follow up visit will be carried out in each patient one month after treatment discontinuation in order to monitor possible withdrawal reactions and collect information on interval events.

FARMITALIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

9.4 Study Timetable

Foreseen start date: March 90
Duration of accrual: 12 months
Foreseen end date (date of the last visit of the last patient): March 92.

10.0 EFFICACY ASSESSMENTS

10.1 Variables to be measured for Efficacy Assessment

At admission and on day 42, after 6 and 12 months of treatment and/or at the time of treatment termination patients will be classified according to the Composite Diagnostic Classification for Depressive Disorders (CODE DD).

On days 0, 7, 14, 21, 28, 35, 42, at bi-weekly intervals afterwards and monthly during follow-up:

- Hamilton Depression Rating Scale (21-item HAMD, enclosure 4); as above plus under screening for entry.
- Clinical Global Impression (Enclosure 5).
- On days 0, 7, 14, 21, 28, 35, 42 and at monthly interval afterwards:
- Montgomery-Asberg Depression Rating Scale (Enclosure 6)
- Zung self-rating Depression Scale (Enclosure 7)

All psychiatric evaluations and ratings will be carried out by the same observer for a given patient, preferably in the same setting and at the same time of the day.

10.2 Efficacy Definitions

Decreases of at least 50 % in the total HAMD score vs day 0 will be considered index of response whereas total HAMD score of 10 or less will be considered index of remission.

Fifty percent increase of HAMD total score with respect to the end of the 6-week open treatment associated with a total score of at least 18 will be considered index of relapse.

10.3 Criteria for Subject Evaluability

Every randomized patient will be included in the analysis.

11.0 SAFETY ASSESSMENT

11.1 Variables to be measured for Safety Assessment

- Standard medical history: at admission.
- Standard clinical examination: full physical examination; chest X-ray: at admission.
- Blood pressure and pulse will be measured in the lying (after 5 minutes lying) and in the standing position (1 - 2 minutes after standing up) in the morning: at admission and at each visit.
- ECG: at admission, day 14, day 28, day 42 and every two months during the double blind treatment phase.
- Ophthalmologic examination: at admission and end of treatment.
- Laboratory tests (Full blood count, serum electrolytes, liver enzymes, blood sugar, SAP, BUN, serum creatinine, uric acid, total and direct bilirubin, total serum proteins and electrophoresis, serum cholesterol and triglycerides; only at admission rT₃, T₃, T₄; urinalysis): at admission, day 14, day 28, day 42 and every two months during the double blind treatment phase.
- Adverse events: a check-list will be administered at baseline and at each visit (Enclosure 8).

11.2 Criteria for Subject Evaluability

Every patient who has received one dose of the experimental treatment will be included in the safety evaluation.

12.0 ADVERSE EVENTS

Patients will be notified of possible adverse events they could experience and instructed to immediately report them to the Investigator.

Any adverse event, noticed by the Investigator or complained of by the patient, including clinically relevant lab abnormalities, will be recorded in the appropriate section of the CRF, regardless of presumed relationship to study medication.

FARMITALIA CARLO ERBA
ERRAMONT GROUP
CNS Line - Medical Research

9550077

For each event, the following information will be entered in the CRF: description, onset date, disappearance date, severity (1 = mild, awareness of sign or symptom, but easily tolerated; 2 = moderate, discomfort enough to cause interference with usual activity; 3 = severe, incapacitating with inability to work or do usual activity; 4 = unknown), drug cause-effect relationship (according to Karch and Lasagna modified criteria; see enclosure 9), outcome, dechallenge (what happened to the adverse event when the drug was stopped or the dose decreased?) rechallenge (what happened when the drug was restarted after the adverse event had disappeared?). The Investigator will also note if the double-blind code has been opened, the action taken regarding the test drug (none, discontinued, dosage reduced) and any treatment applied because of the adverse reactions.

All serious* ("any experience that is (potentially) fatal or life-threatening, disabling, incapacitating, requires inpatient hospitalization, or causes a congenital anomaly or cancer or is due to overdose") and/or unexpected* ("any adverse experience that is not identified in nature, severity or frequency in the current investigator's brochure for the study") adverse events must be immediately (within 24 hours) reported by telephone to FICE Subsidiaries Monitors and the Adverse Event Report Form must be filled in immediately. The same applies to all patients who died, irrespective of whether the event was judged as related to treatment, during the course of the study or within 30 days of completion of treatment.

In case of death, if an autopsy is performed, copy of the pathological report should be sent to the Sponsor.

13.0 EVALUATION SCHEDULE

Is reported in table 1 and table 2.

14.0 STATISTICAL CONSIDERATIONS

Randomized patients will be classified according to the

* Code of Federal Regulation, Vol 21 Part 312. Revised as of April 1, 1987, pg. 75. * J.L.Bem et al.: Review of yellow cards (1986): report to the Committee on the Safety of Medicines. Br.J. Clin. Pharmac. (1988), 26, 679-689.

following criteria:

- Relapse (see 10.2)
- Remission (see 10.2) at the last assessment and at the end of the 1-yr double blind treatment period
- No change (it will be applied to those patients who will complete the one year period of treatment but will not fulfill the above criterion)
- Early termination (see 9.2.3) i.e. patient's request and/or unacceptable toxicity
- Lost to follow-up

The main comparison between treatments will be done on the basis of relapse rate (% of randomized patients experiencing relapse) by using a test based on the binomial distribution. Relapse time will be analysed by Kaplan-Meyer method and the comparison between treatments performed by the log-rank test.

In addition remission rate (% of randomized patients experiencing remission at the last assessment and at the 1-yr interval) in the two treatment groups will be compared.

Frequencies of patients showing maximum decrease ≥ 20 mmHg in the standing systolic blood pressure in the two treatment groups will be compared.

Adverse events will be presented by listing, patient-by-patient, all events encountered and the cumulative frequencies of occurrence by treatment. The latter, if clinically significant, will be submitted to non parametric test of the differences between treatment groups.

Laboratory data will be classified as normal or abnormal on the basis of the normal ranges of the performing Laboratory and the frequency of abnormal results after treatment in the two groups compared.

14.1 Sample Size

Seventy % of the patients are expected to be classified as responders at the end of the initial 6 weeks of treatment and to enter the double blind placebo controlled treatment phase; during the latter 10% of the total patient sample is expected to drop out without reaching the study end point and 50% of the placebo-treated patients are expected to relapse within one year;

FARMACIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

Considering of clinical relevance a difference of 15% in the incidence of relapse with respect to the one expected for the placebo group, 135 patients per arm are necessary in order to have a power (1- β) of at least 0.80 for rejecting the null hypothesis (no difference between treatments) if the alternative hypothesis (relapse rate for placebo = 0.5, for reboxetine \leq 0.35) is true, with the α level fixed at 0.05 (one side).

15.0 ETHICAL ASPECTS

The study will be carried out according to the Helsinki Declaration (Venice revision, Enclosure 10)

15.1 Ethical Committee

This study will not be undertaken until approval is obtained from the Ethical Committee of the participating centres. It is responsibility of the Investigator to submit the study protocol with its attachments to the Ethical Committee.

The written approval of the Ethical Committee will report the name and profession of all its members and a copy of it will be sent to the Sponsor before the study begins.

The Investigator is committed, in compliance with local requirements, to inform the Ethical Committee of any emergent problems, serious adverse reactions or protocol amendments.

15.2 Informed Consent

Before entering the study each patient will be explained nature, duration, and purpose of the study and the action of the compound in such a manner that the patient is aware of the potential risks, inconveniences or adverse effects that may occur and can express his/her informed consent to participation. The consent form (enclosure 1) will be signed by the patient or by the Investigator. In the latter case, the signature of a witness will testify that full information was given to the patient.

FARMITALIA CARLO ERBA
ERBAMONT GROUP
CNS Line - Medical Research

9550077

16.0 PROTOCOL AMENDMENTS

After the protocol has been signed, no changes will be made without the agreement of both the Investigator and the Sponsor. Any change will be recorded on a written agreement which will be signed and dated by both parties and attached to the original protocol.

17.0 STUDY MONITORING

Monitors of the study are:

Dr. M. Bosc (Farmitalia Carlo Erba Tour Franklin Cedex 11 Paris La Defense - France - Phone: 49032000)

Dr. G. Fiorentino (Farmitalia Carlo Erba, Apartado 10744 Panama 4, Rep. Panama. Phone: 642133)

Dr. M. Geller (Farmitalia Carlo Erba, Rodovia Washington Luiz Br-040 Km 119, 293 Duque de Caxias, Rio de Janeiro, Brasil. Phone: 7715110)

Dr. L. Orlandini (Farmitalia Carlo Erba ROSCA, Karlsplatz 1, A 1010 Wien, Austria. Phone: 5054651)

Dr. F. Heteny (Farmitalia Carlo Erba, Képviselet Iroda Bajcsy Zsilinszky ut 12 VI S 1051 Budapest, Hungary. Phone: 1181376)

A pre-study visit will be made by the Monitor to the Investigator in order to discuss problems, if any, and the obligations of both the Sponsor and the Investigator. During the trial monitoring visits will be paid to the site by the study Monitor monthly to bi-monthly. During the visits the Monitor will assess the progress of the study, review the compliance with the study protocol, discuss any problem, check the CRFs for legibility, accuracy and completeness, validate CRFs content against source documents, assess the status of drug storage dispensing and retrieval.

Operating procedures for training on assessment instruments, study monitoring and coordination are described in attachment A.

18.0 SUPPLY AND INVENTORY

Test preparation will be supplied by Farmitalia Carlo Erba in the form described in 8.1. Records will be kept by the Investigator as to the disposition of study drug for each

FARMITALIA CARLO ERBA
ERRAMONT GROUP
CNS Line - Medical Research

9550077

patient. A disposition form accounting for all study supplies will be signed by the Investigator.

19.0 ADMINISTRATIVE ASPECTS

19.1 Insurance Policy

Farmitalia Carlo Erba Company declares to have a group insurance cover (policy NO. 4W8102 - Italia Assicurazioni) which provides indemnity to the Investigator, to the co-Investigators and to the subjects participating in the trial.

19.2 Curriculum Vitae

The Investigator will provide the Sponsor with signed copies of his/her and his/her co- Investigators CVs.

19.3 Data Collection in the Case Record Form

All study data will be recorded in the CRF supplied by the Sponsor (Attachment B). A black ink ball point pen should be used for entering the data to ensure the good quality of the reproduced CRFs copies.

Only the Principal Investigator and the duly authorized co-Investigators can make entries in the CRF.

In case of errors corrections must be made by crossing out the incorrect entry (that must remain legible) and entering the correction followed by the Investigator's initials and the date of the correction.

On the occasion of the monitoring visits the monitor will take away the original and one copy of each page, while the Investigator will retain a copy for his files, together with the drug disposition records, for ten years after the discontinuation of the investigation.

19.4 Use of the Information related to the Study

All unpublished documentation including the protocol, the CRF and the Investigator's Brochure, given to the Investigator is confidential. These documents cannot be disclosed to a third party without the written consent of FICE R&D. The submission of these documents to the Ethical Committee is expressly permitted.

The Investigator agrees that FICE R&D maintains the right to utilize the results of this study, in their original form and/or in a global report, for submission to the governmental and regulatory authorities of any country.

20.0 STUDY REPORT

20.1 Clinical Study Final Report

The final Medical Study Report will be written by the Product Leader and will be submitted to the Investigators for approval and signature.

20.2 Publication of Study Results

The results of the study will be published in a common publication, agreed upon between all Investigators and FICE R&D.

The Investigators, whilst free to use the data resulting from this study for individual publications (subsequent to the common one), are asked to discuss any paper with Farmitalia Carlo Erba prior to submission; to this purpose copy of manuscript/abstract has to be available for FICE R&D Approval Procedure 30 days prior to publication.

The results of the study may be submitted for a common publication, agreed upon between the Investigator and FICE R&D.

21.0 END OF THE STUDY

Either the Investigator or FICE R&D could terminate this study at any time for well documented reasons. In this event the other party will be immediately notified.

22.0 STUDY COORDINATION

A Steering Committee in charge of the coordination of the study will be settled, as described in Attachment A.

ENCLOSURE Nº 1

REBOXETINE PROTOCOL 20124/013

Phase III controlled study of the activity and tolerability of reboxetine in comparison with placebo in the continuation therapy of patients suffering for major depressive disorders.

CONSENT FORM

Principal Investigator:

EXPLANATION

Purpose of the study

Reboxetine, a new potential antidepressant agent, has effects in animals which suggest that it may exert therapeutic efficacy of faster onset, in comparison with established antidepressant drugs, in patients suffering from depressive disorders. The trial is proposed in order to learn about the antidepressant effectiveness of the compound and about the maintenance of its activity.

Plan of the study

After a six-weeks treatment course with reboxetine at the daily dose of 8 mg, patients responding to the treatment will receive either reboxetine or a harmless inactive treatment (placebo). Neither patients nor doctors will know which treatment will be administered in individual cases until after the study is completed. The identity of the treatments can anyhow be determined immediately if any medical problem will develop and it will become important to learn which of the two possible treatments is being given.

Treatment will be administered for a maximum period of one year. It will be discontinued in case of re-emergence of psychiatric symptomatology or in case of significant side-effects. In addition patients participating in the study may withdraw their consent at any time without prejudice to their continued medical treatment.

During treatment, physical and psychiatric examinations will be done on frequent occasions, in order to determine

9550077

PROT.Nº 20124/013

CONT' ENCLOSURE Nº1

possible side-effects and benefits of treatments. Blood tests, urinalysis, ECG will be undertaken bi-weekly during the initial phase or every two months during the long-term treatment phase. Blood pressure and pulse will be taken very frequently, particularly in the first two weeks of treatment.

Possible discomforts and risks

Antidepressant drugs can cause dry mouth, blurred vision, dizziness, mild difficulty in voiding urine, postural hypotension and electrocardiographic changes.

Reboxetine has been so far administered for 28 days to about 180 patients and was well tolerated up to the dose of 5 mg twice daily. In the dose range of 3-5 mg twice daily clinically relevant improvement of depressive condition was present in the majority of patients; symptoms complained off by patients were mainly mild and transient and included most frequently headache, sweating, lassitude, nasal congestion, constipation and urinary hesitancy. At higher doses orthostatic hypotension, tachycardia, dizziness, blurred vision and nausea were reported.

Patients participating in the study will be carefully monitored to detect early signs of such side-effects.

Possible benefits

Other drugs are available for treatment of depressive disorders but none has been of proven value in all cases. This study will allow the evaluation of the antidepressant activity of reboxetine in comparison with placebo upon long-term administration. Under the latter treatment, 50% maintenance of response can be expected upon long-term administration. The evaluation of patient response under placebo could be useful in deciding the most appropriate treatment approach in individual cases.

Alternative treatment

Patients would receive alternative pharmacological therapy with an antidepressant drug chosen on the basis of response during previous episodes, if any. Risks and benefits of receiving treatment with any of the available antidepressant drugs can be explained by.....

Confidentiality

Participation in the study will be kept confidential to the extent permitted by law.

9550077

PROT. N°20124/013

CONT'. ENCLOSURE N° 1

Problems and questions

Should any problem or question arise with regard to the study, patients can contact the Principal Investigator:

.....
or the other staff members also involved in the study:

.....

.....

.....

In addition any problem or question can be discussed with a member of the Institutional Review Board (.....), the Committee which has evaluated the potential risks and possible benefits of the study.

Payments and policy regarding research-related injuries.

Patients will not be paid for the participation in the study. The Clinical Center will provide short-term medical care for any physical injury resulting from participation in the study. No long-term medical care or financial compensation for such injuries will be provided except as it may be through whatever remedies are normally available under law. Insurance coverage is granted through the Sponsor Company.

PATIENTS CONSENT

I have read the explanation about this study and I have been given the opportunity to discuss it and to ask questions. I hereby consent to take part in this study.

CONT. ENCLOSURE N°4

16. Loss of weight Rate either A or B

A. When Rating By History:

- 0 No weight loss
 1 Probable weight loss associated with present illness
 2 Definite (according to patient) weight loss
 3 Not assessed

B. On Weekly Ratings By Ward Psychiatrist, When Actual Weight Changes Are Measured:

- 0 Less than 1 lb. weight loss in week
 1 Greater than 1 lb. weight loss in week
 2 Greater than 2 lb. weight loss in week
 3 Not assessed

17. Insight

- 0 Acknowledges being depressed and ill
 1 Acknowledges illness but attributes cause to bad food, climate, overwork, virus, need for rest, etc.
 2 Denies being ill at all

8. Diurnal variation

A. Note Whether Symptoms Are Worse In Morning Or Evening. If NO Diurnal Variation, Mark "none":

- 0 No variation 1 Worse in A.M. 2 Worse in P.M.

B. When Present, Mark The Severity Of The Variation. Mark "None" If NO Variation:

- 0 None 1 Mild 2 Severe

9. Depersonalization and derealization (Such as: Feelings of unreality, Nihilistic ideas)

- 0 Absent 1 Mild 2 Moderate
 3 Severe 4 Incapacitating

20. Paranoid symptoms

- 0 None
 1 Suspicious
 2 Ideas of reference
 3 Delusions of reference and persecution

1. Obsessional and compulsive symptoms

- 0 Absent 1 Mild 2 Severe

CLINICAL GLOBAL IMPRESSION (CGI)

ENCLOSURE N°5

A. SEVERITY OF ILLNESS

Considering your clinical experience with this particular population, how mentally ill is the patient at this time?

- 1 Normal, not at all ill
- 2 Borderline mentally ill
- 3 Mildly ill
- 4 Moderately ill
- 5 Markedly ill
- 7 Severely ill
- 8 Among the most extremely ill patients

B. GLOBAL IMPROVEMENT (rate total improvement whether or not, in your judgement, it is due entirely to drug treatment)

Compared to this condition at admission to the study, how much has he changed?

- 1 Very much improved
- 2 Much improved
- 3 Minimally improved
- 4 No change
- 5 Minimally worse
- 6 Much worse
- 7 Very much worse

C. EFFICACY INDEX (rate this item on the basis of drug effect only)

Activity	Tolerability: side effects			
	None	Do not significantly interfere with patient's functioning	Significantly interfere with patient's functioning	Outweigh therapeutic effect
MARKED Vast improvement, complete or nearly complete remission of all symptoms	1	2	3	4
MODERATE Decided improvement, partial remission of symptoms	5	6	7	8
MINIMAL Slight improvement which does not alter status of care of patient	9	10	11	12
UNCHANGED OR WORSE	13	14	15	16

ENCLOSURE No 6

MADRS: MONTGOMERY ASBERG DEPRESSION RATING SCALE

1. Reported sadness

- Representing subjectively experienced mood, regardless of whether it is reflected in appearance or not. Includes depressed mood, low spirits, despondency, and the feeling of being beyond help and without hope.
- Rate according to intensity, duration and the extent to which the mood is influenced by events.
- Elated mood is scored zero on this item.

Occasional sadness may occur in the circumstances [0]; Predominant feelings of sadness, but brighter moments occur [1]; Pervasive feelings of sadness or gloominess, the mood is hardly influenced by external circumstances [2]; Continuous experience of misery or extreme despondency [3].

2. Inner tension

- Representing feelings of ill-defined discomfort, edginess, inner turmoil, mental tension mounting to panic, dread and anguish.
- Rate according to intensity, frequency, duration and the extent of reassurance called for.
- Distinguish from sadness, worrying and muscular tension.

Placid, only fleeting inner tension [0]; Occasional feelings of edginess and ill-defined discomfort [1]; Continuous feelings of inner tension, or intermittent panic which the patient can only master with some difficulty [2]; Unrelenting dread or anguish, overwhelming panic [3].

3. Apparent sadness

- Representing despondency, gloom, and despair (more than just ordinary transient low spirits) reflected in speech, facial expression, and posture, rate by depth and inability to brighten up.

No sadness [0]; Looks dispirited but brightens up occasionally [1]; Appears sad and unhappy all of the time [2]; Extreme and continuous gloom and despondency [3].

4. Suicidal thoughts

- Representing the feeling that life is not worth living, that a natural death would be welcome, suicidal thoughts, and preparations for suicide.
- Suicidal attempts should not in themselves influence the rating.

Enjoys life or takes it as it comes [0]; Weary of life, only fleeting suicidal thoughts [1]; Much better off dead. Suicidal thoughts are common, and suicide is considered as a possible solution, but without specific plans or intention [2]; Explicit plans for suicide when there is an opportunity, active preparation for suicide [3].

5. Inertia

- Representing a difficulty getting started or slowness initiating and performing everyday activities
- Distinguish from indecision and fatigability.

No difficulty in getting started. No sluggishness [0]; Difficulties in starting new activities [1]; Difficulties in starting very simple routine activities, which are carried out only with effort [2]; Complete inertia, unable to start any activity without help [3].

6. Inability to feel

- Representing the subjective experience of reduced interest in the surroundings, or activities that normally give pleasure. The ability to react with adequate emotion to circumstances or people is produced.
- Distinguish from inertia

Normal interest in the surroundings and in other people [0]; Reduced ability to enjoy usual interests. Reduced ability to feel anger [1]; loss of interest in the surroundings. Loss of feelings for friends and acquaintances [2]; The experience of being emotionally paralyzed, inability to feel anger or grief, and a complete or even painful failure to feel for close relatives and friends [3].

CONT. ENCLOSURE N°6

7. Pessimistic thoughts

- Representing thoughts of guilt, inferiority, self-reproach, sinfulness, remorse and ruin.

No pessimistic thoughts [0]; fluctuating ideas of failure, self-reproach or self-depreciation [1]; Persistent self-accusations, or definite but still rational ideas of guilt or sin. Increasingly pessimistic about the future [2];

Delusions of ruin, remorse and unredeemable sin. Absurd self-accusations [3].

8. Concentration difficulties

- Representing difficulties in collecting one's thoughts amounting to incapacitating lack of concentration.

- Rate according to intensity, frequency, and degree of incapacity recorded.

- Distinguish from failing memory and disrupted thought.

No difficulties in concentrating [0]; Occasional difficulties in collecting one's thoughts [1]; Difficulties in concentrating and sustaining thoughts which interfere with reading or conversation [2]; Incapacitating lack of concentration [3].

9. Reduced sleep

- Representing a subjective experience of reduced duration or depth of sleep compared to the subject's own fitful sleep.

Sleep as usual [0]; Slight difficulty dropping off to sleep or slightly reduced, light or fitful sleep [1]; sleep reduced or broken by at least 2 hours [2]; Less than two or three hours sleep [3].

10. Reduced appetite

- Representing the feeling of a loss of appetite compared with when well.

Normal or increased appetite [0]; Slightly reduced appetite [1]; No appetite. Food is tasteless. Need to force oneself to eat [2]; Must be forced to eat. Food refusal [3].

Attachment A

REBOXETINE PROTOCOL 20124/013: OPERATING PROCEDURES FOR TRAINING ON ASSESSMENT INSTRUMENTS, STUDY MONITORING AND COORDINATION.

Aim

The purpose of these procedures is to provide standardization of the study conduct in the different clinical centers and to assure data uniformity and compatibility by appropriate interventions during data gathering.

Inter-rater reliability

Prior to commencement of the clinical trial:

- training on diagnostic assessments will be conducted during the first Investigator-meeting and first site visit.

During the clinical trial:

- inter-rater agreement for the instruments used in the assessment of change will be tested on the occasion of the monitoring visits by employing 4 videotaped interviews.

Study monitoring

During the course of the study (24-months) one monitoring visit will be conducted by the Scientific Coordinator of the study (Prof. T. Ban) and monthly to bi-monthly monitoring visits will be conducted by Study Monitors from Farmitalia Carlo Erba.

The start-up visit will take place after approval of the protocol by the Institutional Review Board (IRB) or Ethical Committee. On this visit the following documents will be collected:

- copy of the protocol signed by the Principal Investigator;
- CV of Principal Investigator and Co-Investigators;
- the written approval of the study (typed on the Institute's letter head) by the Hospital or University Center Review Board and the IRB members list;

9550077

Prot. N° 20124/013 Cont. Attachment A

- an IRB approved blank copy of the consent form;
- the list of the laboratory normal values or ranges of the lab. tests.

These documents will be sent to FICE-Milan (A. Faja). On the occasion of this visit the monitor will also check that the CRFs and the drug supply have been delivered to the Clinical Investigator and the accompanying letter, signed by the Clinical Investigator, will be collected. In addition the Monitor will identify the staff members who will be involved in the study conduct and the monitoring visits schedule will be agreed.

Following the start-up visit the form A (enclosed) will be filled in. Copy of it will be sent to A. Faja in Milan.

The first monitoring visit will be done immediately after the recruitment of the first two, three patients.

The periodic monitoring visits are carried out in order to:

- 1 verify protocol adherence: patient eligibility (page 1 of the CRF), times of assessments, completeness of data, pill count;
 - 2 verify data consistency looking for inconsistencies or errors in the data recorded on the CRF;
 - 3 verify the accuracy of data collection in CRFs against the original clinic or hospital records for:
 - pt initials and hospital record no
 - signed informed consent
 - study medication administration and concomitant medications
 - physician notes on adverse events
 - 20% of data for laboratory tests, patient history and vital signs; in case of an error rate > 15% all data need to be monitored;
 - total Hamilton score reported in the hospital record.
- Source-verified data can be initialled by the study monitor in the CRF.
- 4 review all adverse events including laboratory abnormalities, occurred since the previous visit. Should the information of a serious, or unexpected adverse event newly emerge, the local study Monitor

9550077

Prot. N° 20124/013

Cont. Attachment A

must immediately (within two working days) inform the Product Leader in Milan;

- 5 evaluate patient recruitment rate and treatment discontinuations;
- 6 verify study medication storage and accountability and collect bottles of completed treatments;
- 7 ensure continued acceptability of the facilities and of the staff.

CRFs will be completed in black ink and corrections, if needed, made only by the Clinical Investigator with a single line throughout; the corrections will be initialled by Clinical Investigator and dated. Each page of each completed CRF will be signed by Clinical Investigator.

After review for accuracy and completeness, the original and first copy of each page of the CRF will be removed (leaving the second copy with the Investigator). The first copy will be sent to Milan by Special Delivery Service for review and data processing while the original will be retained by the Monitor in the subsidiary until completion of the whole treatment period of the individual patient.

After each monitoring visit the periodic site visit report and the patients progress report form (form B and C enclosed) will be filled in. Copy of them will be sent to A. Faja in Milan.

The study termination visit will be performed upon Investigator's completion of all CRFs of treated patients. During this visit:

- 1 the monitor will check and collect the remaining completed CRFs and will perform a final data review;
- 2 a final check and review of drug accounting, inventorying of remaining drug supplies and arrangement to send them to FICE will be done;
- 3 a time frame for study reporting will be discussed;
- 4 appropriate follow-up of patients under long-term treatment will be assured and monitoring and collection of data from these patients discussed and agreed

The study termination visit form (form D) will be filled in and copy of it sent to A. Faja.

9550077

Prot. N° 20124/013

Cont. Attachment A

Study coordination

In order to obtain uniformity and standardization in the carrying out of the study a Steering Committee is established. All questions arising during the conduct of the study will be submitted to the Committee for advice and action taking.

In particular the Committee will take care of:

- queries about patients acceptability
- possible need of protocol amendments
- possible need of premature termination of the study
- acceptability of particular cases of protocol violations
- evaluation of clinically relevant adverse events and their scientific and ethical consequences in terms of issues raised or study discontinuation.

Members of the Committee will be: Prof. T. Ban (Vanderbilt University), Chairman; Dr. I. Cohen, legal aspects; Dr. L. Morey (biometric aspects).

Any problem or issue arising during the conduct of the study will be submitted to the Committee in writing by the Clinical Investigators or by the study Monitors. "Ad hoc" meetings of the Committee will be organized when needed. File note of the meeting with conclusions about action taking will be circulated to Clinical Investigators and study Monitors.

APPENDIX 2

ADVERSE DRUG REACTION - A CRITICAL REVIEW

GUIDELINES FOR DETERMINING CAUSE-EFFECT RELATIONSHIP
(According to Karch and Lasagna, JAMA 234: 1236-41,1975, modified)

1. DEFINITE (or CERTAIN)

A reaction that follows a reasonable temporal sequence from administration of the drug or in which the drug level has been established in body fluids or tissues; that follows a known response pattern to the suspected drug; and that is confirmed by improvement on stopping the drug (dechallenge), and reappearance of the reaction on repeated exposure (rechallenge).

2. PROBABLE

A reaction that follows a reasonable temporal sequence from administration of the drug; that follows a known response pattern to the suspected drug; that is confirmed by dechallenge; and that could not be reasonably explained by the known characteristics of the patient's clinical state.

3. POSSIBLE

A reaction that follows a reasonable temporal sequence from administration of the drug; that follows a known response pattern to the suspected drug; but that could have been produced by the patient's clinical state or other modes of therapy administered to the patient.

4. DOUBTFUL

Any reaction that does not meet the criteria above and is not judged as not drug related or unknown.

5. UNKNOWN

Relationship for which no evaluation can be made.

6. NOT DRUG RELATED

Any reaction that is judged as definitely due to conditions (causes) different from the drug.

CORPORATE MEDICAL COORDINATION

Enclosure 10

DECLARATION OF HELSINKI

Recommendations guiding physicians in biomedical research involving human subjects

Adopted by the 18th World Medical Assembly, Helsinki, Finland, June 1964, amended by the 29th World Medical Assembly, Tokyo, Japan, October 1975, and the 35th World Medical Assembly, Venice, Italy, October 1983.

INTRODUCTION

It is the mission of the physician to safeguard the health of the people. His or her knowledge and conscience are dedicated to the fulfilment of this mission.

The declaration of Geneva of the World Medical Association binds the physician with the words, "The health of my patient will be my first consideration", and The International Code of Medical Ethics declares that, "A physician shall act only in the patient's interest when providing medical care which might have the effect of weakening the physical and mental condition of the patient".

The purpose of biomedical research involving human subjects must be to improve diagnostic, therapeutic and prophylactic procedures and the understanding of the aetiology and pathogenesis of disease.

In current medical practice most diagnostic, therapeutic or prophylactic procedures involve hazards. This applies especially to biomedical research.

Medical progress is based on research which ultimately must rest in part on experimentation involving human subjects.

In the field of biomedical research a fundamental distinction must be recognized between medical research in which the aim is essentially diagnostic or therapeutic for a patient, and medical research the essential object of which is purely scientific and without implying direct diagnostic or therapeutic value to the person subjected to the research.

Special caution must be exercised in the conduct of research which may affect the environment, and the welfare of animals used for research must be respected.

CORPORATE MEDICAL COORDINATION

cont. Encl. 10

Because it is essential that the results of laboratory experiments be applied to human beings to further scientific knowledge and to help suffering humanity, The World Medical Association has prepared the following recommendations as a guide to every physician in biomedical research involving human subjects. They should be kept under review in the future. It must be stressed that the standards as drafted are only a guide to physicians all over the world. Physicians are not relieved from criminal, civil and ethical responsibilities under the law of their own countries.

I. BASIC PRINCIPLES

1. Biomedical research involving human subjects must conform to generally accepted scientific principles and should be based on adequately performed laboratory and animal experimentation and on a thorough knowledge of the scientific literature.
2. The design and performance of each experimental procedure involving human subjects should be clearly formulated in an experimental protocol which should be transmitted to a specially appointed independent committee for consideration, comment and guidance.
3. Biomedical research involving human subjects should be conducted only by scientifically qualified persons and under the supervision of a clinically competent medical person. The responsibility for the human subject must always rest with a medically qualified person and never rest on the subject of the research, even though the subject has given his or her consent.
4. Biomedical research involving human subjects cannot legitimately be carried out unless the importance of the objective is in proportion to the inherent risk to the subject.
5. Every biomedical research project involving human subjects should be preceded by careful assessment of predictable risks in comparison with foreseeable benefits to the subject or to others. Concern for the interests of the subject must always prevail over the interests of science and society.
6. The right of the research subject to safeguard his or her integrity must always be respected. Every precaution should be taken to respect the privacy of the subject and to minimize the impact of the study on the subject's physical and mental integrity and on the personality of the subject.
7. Physicians should abstain from engaging in research projects involving human subjects unless they are satisfied that the hazards involved are believed to be predictable. Physicians should cease any investigation if the hazards are found to outweigh the potential benefits.

FACULTY LIAISON
MONTMONT GROUP

9550077

CORPORATE MEDICAL COORDINATION

cont. Encl. 10

8. In publication of the results of this or her research, the physician is obliged to preserve the accuracy of the results. Reports of experimentation not in accordance with the principles laid down in this Declaration should not be accepted for publication.

9. In any research on human beings, each potential subject must be adequately informed of the aims, methods, anticipated benefits and potential hazards of the study and the discomfort it may entail. He or she should be informed that he or she is at liberty to abstain from participation in the study and that he or she is free to withdraw his or her consent to participation at any time. The physician should then obtain the subject's freely given informed consent, preferably in writing.

10. When obtaining informed consent for the research project the physician should be particularly cautious if the subject is in a dependent relationship to him or her or may consent under duress. In that case the informed consent should be obtained by a physician who is not engaged in the investigation and who is completely independent of this official relationship.

11. In case of legal incompetence, informed consent should be obtained from the legal guardian in accordance with national legislation. Where physical or mental incapacity makes it impossible to obtain informed consent, or when the subject is a minor, permission from the responsible relative replaces that of the subject in accordance with national legislation. Whenever the minor child is in fact able to give a consent, the minor's consent must be obtained in addition to the consent of the minor's legal guardian.

12. The research protocol should always contain a statement of the ethical considerations involved and should indicate that the principles enunciated in the present declaration are complied with.

II. MEDICAL RESEARCH COMBINED WITH PROFESSIONAL CARE (Clinical research)

1. In the treatment of the sick person, the physician must be free to use a new diagnostic and therapeutic measure, if in his or her judgement it offers hope of saving life, reestablishing health or alleviating suffering.

2. The potential benefits, hazards and discomfort of a new method should be weighed against the advantages of the best current diagnostic and therapeutic methods.

3. In any medical study, every patient - including those of a control group, if any - should be assured of the best proven diagnostic and therapeutic method.

4. The refusal of the patient to participate in a study must never interfere with the physician-patient relationship.

FARMITALIA CARLO ERBA
ERBAMONT GROUP

9550077

CORPORATE MEDICAL COORDINATION

Cont. Encl. 10

5. If the physician considers it essential not to obtain informed consent, the specific reasons for this proposal should be stated in the experimental protocol for transmission to the independent committee (1,2).

6. The physician can combine medical research with professional care, the objective being the acquisition of new medical knowledge, only to the extent that medical research is justified by its potential diagnostic or therapeutic value for the patient.

III. NON-THERAPEUTIC BIOMEDICAL RESEARCH INVOLVING HUMAN SUBJECTS

(Non-clinical biomedical research)

1. In the purely scientific application of medical research carried out on a human being, it is the duty of the physician to remain the protector of the life and health of that person on whom biomedical research is being carried out.

2. The subjects should be volunteers - either healthy persons or patients for whom the experimental design is not related to the patient's illness.

3. The investigator or the investigating team should discontinue the research if in his/her or their judgement it may, if continued, be harmful to the individual.

4. In research on man, the interest of science and society should never take precedence over considerations related to the well-being of the subject.

REBOXETINE 4 mg tablets

Batch SF 1032

Manufacturing date : June, 1989
Expiry date : May, 1993
Active drug substance : RR 16N055
Appearance : round, convex, 8 mm diameter,
white tablet with a breakline
on one surface, and marked S.F.
on the other
Identification : positive
Average weight : mg 199.33
Uniformity of content : within the limits, according to Eur.
Ph. 2nd Ed., section V.5.2.2
Assay : mg 3.967 of Reboxetine/tablet
Related substances : 0.72%
Dissolution : 92.86% of the L.A. after 15 minutes
Microbial contamination : total viable aerobic count < 1000
moulds and yeasts < 100
E. Coli and Salmonellae : absent
Reanalysis date : November 18th, 1992

NOTE : this certificate replaces the previous one, edited on
April 27th 1992, owing to the extension of the shelf-life

12.1.9 ECG CODES

ECG CODES

0 Normal

1 Rhythm disorders

- 10 Sinus bradycardia (< 60)
- 20 Sinus tachycardia (> 100)
- 30 Sick Sinus Syndrome
- 40
 - Atrial ectopic beats:
 - 41 - Occasional
 - 42 - Frequent (> 6/mm)
 - 43 - Couplets
 - 44 - Supraventricular Tachycardia
- 50
 - Ventricular ectopic beats:
 - 51 - Occasional
 - 52 - Frequent (> 6/mm)
 - 53 - Polymorphic
 - 54 - Couplets
 - 55 - Ventricular Tachycardia
- 60
 - Atrial fibrillation/flutter
- 105
 - Vagotonia
- 108
 - Atrial-ventricular dissociation

2 Conduction disorders

- 70
 - A-V Block
 - 71 - 1st degree
 - 72 - 2nd degree - Mobitz 1
 - 73 - Complete - Mobitz 2
- 85
 - Right bundle branch block
- 86
 - Left bundle branch block
- 87
 - Left anterior hemiblock
- 88
 - Left posterior hemiblock
- 89
 - Bifascicular Block (specify)
- 90
 - Trifascicular Block (specify)
- 91
 - Conduction disorders
- 103
 - Left axial deviation
- 106
 - Right incomplete bundle branch block

3 Ischemic signs

- 102
 - Repolarization disturbances
- 107
 - Non specific ST-T changes
- 82
 - Myocardial ischemia
- 84
 - Acute Myocardial infarction

4 Other

- 80
 - Left ventricular hypertrophy
- 81
 - Right ventricular hypertrophy
- 83
 - Previous Myocardial infarction
- 93
 - Other (specify) _____
- 104
 - Right axial deviation

12.2.1 SERIOUS ADVERSE EVENTS - CASE HISTORIES

9550077

Pharmacia

Document 9550077

Narrative of Event no. HU 001 Protocol no. 20124/013 Patient no. 18/109

Center no. 12, Kecskemet (Hungary)

Investigator: E. Kovacs

Adverse event: hallucinations (date of the event: 23.05.92)

Patient's history: the patient was a 51 years old male and he was suffering from a Major Depressive Episode for 8 months when he entered in the 20124/013 study on January 9th, 1992. He had had the onset of depressive disorder at the age of 47 years. His previous antidepressive treatments were represented by trimipramine, dibenzepin hydrochloride and maprotiline.

The patient had had a gastroduodenostomia in 1988.

Baseline ECG showed sinus bradycardia while chest X-ray was normal. Laboratory tests did not show any clinical relevant abnormalities.

Experimental period: the patient entered the 20124/013 study on January 9th, 1992 and received the experimental treatment as follows:

treatment	days	dose	remarks
from - to		(mg/day)	
15.01.92 - 28.01.92	14	8	
29.01.92 - 25.02.92	28	4	
26.02.92 - 22.05.92	87	0	
23.05.92 - 23.05.92	1	0	

On January 15th, 1992 he started a therapy with chloral hydrate (1500 mg/day) for insomnia.

On January 17th, 1992 a picture of urinary retention of moderate severity appeared, treated with drotaverine hydrochloride (40 mg/day) till 30.01.92. The dosage of the experimental treatment was reduced with full recovery on 29.01.92.

On February 25th, 1992, according to the protocol, the patient completed the open phase of treatment with reboxetine. At this moment the Hamilton Depression Rating scale (HAMD) was performed and the total score was of 16 points. In comparison with the baseline score (29 points) an improvement was observed.

On February 26th, 1992 he was included in a double-blind treatment period. The improvement in depressive symptomatology was maintained till the middle of May.

On May 23rd, 1992 the patient suffered from hallucinations that led to his hospitalization. The experimental treatment, which happened to be placebo, was stopped.

During the study the patient had received the experimental treatment for 42 days, taking a cumulative amount of 224 mg of reboxetine.

Comments: the Investigator judged the event as probably drug related.

Document 9550077

Narrative of Event no. HU 002 Protocol no. 20124/013 Patient no. 30
Center no. 12, Kecskemet (Hungary) Investigator: A. Szucs
Adverse event: suicide by overdose of multiple drugs (date of the event: 03.04.92)

Patient's history: the patient was a 36 years old female and she was suffering from a Major Depressive Episode for 2 months when she entered in the 20124/013 study on February 24th, 1992. She had had the onset of depressive disorder at the age of 34 years. Her previous antidepressive treatments were represented by amitriptyline, lithium carbonate and maprotiline till February 18th, 1992 with very poor results. In addition she was treated with levomepromazine (75 mg/day) from January 9th, 1992 to February 18th, 1992.

Baseline ECG and chest X-ray were normal. Laboratory tests did not show any clinical relevant abnormalities.

Experimental period: the patient entered the 20124/013 study on February 24th, 1992 and received the experimental treatment as follows:

treatment	days	dose	remarks
from - to		(mg/day)	
25.02.92 03.04.92	39	8	

On February 25th, 1992 she started a therapy with chloral hydrate (1000 mg/day) and valerianae comp. (400 mg/day) for insomnia.

At the baseline visit the Hamilton Depression Rating scale (HAM-D) was performed and the total score was of 42 points. While she was on therapy a progressive improvement was observed in the severity of the depressive syndrome until March 3rd, 1992 when the HAM-D total score of 21 points was reported. At the same time no suicidal intent was detected.

On April 3rd, 1992 was at home and committed suicide by taking alcohol and drugs (levomepromazine, promethazine, amitriptyline and maprotiline). Autopsy was performed according to the request of local police department and death was ascribed to respiratory paralysis due to drug intoxication. The results of toxicology examination confirmed that the drugs ingested were those mentioned. The blood alcoholemia was of 1.75 g/l %.

At the moment of the event the patient had been under the experimental treatment for 39 days and she had received a cumulative amount of 312 mg of reboxetine, while being treated with 8 mg/day of the compound.

Comments: the Investigator judged the adverse event as not drug related.

Pharmacia

Document 9550077

Narrative of Event No. **FR 0075** Protocol no. **20124/013** Patient no. **11**

Center no. **3, Marseille (France)** Investigator: **d'Arnaud Castiglioni**

Adverse event: **generalized epilepsy fit** (date of the event: **27.05.91**)

Patient's history: the patient was a 56 years old female and she was suffering from a Major Depressive Episode for 5 months when she entered in the 20124/013 study on May 17th, 1991. She had had the onset of depressive disorder at the age of 49 years.

The patient had suffered from moderate hallucinatory delirium between 1988 and February 1991 and for this reason she has been treated with haloperidol (6 mg/day). She complained of insomnia treated with meprazine (410 mg/day) and clorazepate/ promazine/promazine (10 mg/day) from February 15th, 1991 to May 23rd, 1991.

Baseline ECG and chest X-ray were normal. Laboratory tests did not show any clinical relevant abnormalities.

Experimental period: the patient entered the 20124/013 study on May 17th, 1991 and received the experimental treatment as follows:

treatment	days	dose	remarks
from - to		(mg/day)	
25.05.91 - 27.05.91	3	8	

From May 24th, to May 27th, 1991 she was treated with chloral hydrate (500 mg/day) for insomnia.

On May 27th, 1991, four hours after the last dose of reboxetine, the patient suffered from a single episode of generalized epilepsy fit, recovering spontaneously in a few minutes.

The experimental treatment was definitively discontinued.

On May 28th, 1991 an EEG was performed and slow waves (delta intermittent activity) in the anterior and average temporal region of the left hemisphere were found.

On June 6th, 1991 another EEG was done and the result was normal. Also a neurological examination was performed showing a normal clinical picture with the exception for an extrapyramidal hypertonia that was considered as probably correlated with the previous therapy with haloperidol.

At the moment of the event the patient had been under the experimental treatment for 3 days and she had received a cumulative amount of 24 mg of reboxetine, while being treated with 8 mg/day of the compound.

Comments: the Investigator judged the adverse event as not drug related. Among psychotropic drugs tricyclic antidepressant and neuroleptics are known to be associated with convulsions. The sudden stopping of benzodiazepine treatment is probably the main factor responsible of the epilepsy fit.
